61922. **comment:** ** CAPI3REF: OS Interface File Virtual Methods Object *** Every file opened by the [sqlite3_vfs.xOpen] method populates an ** [sqlite3_file] object (or, more commonly, a subclass of the ** [sqlite3_file] object) with a pointer to an instance of this object. ** This object defines the methods used to perform various operations ** against the open file represented by the [sqlite3_file] object. *** If the [sqlite3_vfs.xOpen] method sets the sqlite3_file.pMethods element ** to a non-NULL pointer, then the sqlite3_io_methods.xClose method ** may be invoked even if the [sqlite3_vfs.xOpen] reported that it failed. The ** only way to prevent a call to xClose following a failed [sqlite3_vfs.xOpen] ** is for the [sqlite3_vfs.xOpen] to set the sqlite3_file.pMethods element ** to NULL. *** The flags argument to xSync may be one of [SQLITE_SYNC_NORMAL] or ** [SQLITE_SYNC_FULL]. The first choice is the normal fsync(). ** The second choice is a Mac OS X style fullsync. The [SQLITE_SYNC_DATAONLY] ** flag may be ORed in to indicate that only the data of the file ** and not its inode needs to be synced. *** The integer values to xLock() and xUnlock() are one of ** ** [SQLITE_LOCK_NONE], ** [SQLITE_LOCK_SHARED], ** [SQLITE_LOCK_RESERVED], ** [SQLITE_LOCK_PENDING], or ** [SQLITE_LOCK_EXCLUSIVE]. ** ** xLock() increases the lock. xUnlock() decreases the lock. ** The xCheckReservedLock() method checks whether any database connection, ** either in this process or in some other process, is holding a RESERVED, ** PENDING, or EXCLUSIVE lock on the file. It returns true ** if such a lock exists and false otherwise. *** ** The xFileControl() method is a generic interface that allows custom ** VFS implementations to directly control an open file using the ** [sqlite3_file_control()] interface. The second "op" argument is an ** integer opcode. The third argument is a generic pointer intended to ** point to a structure that may contain arguments or space in which to ** write return values. Potential uses for xFileControl() might be ** functions to enable blocking locks with timeouts, to change the ** locking strategy (for example to use dot-file locks), to inquire ** about the status of a lock, or to break stale locks. The SQLite ** core reserves all opcodes less than 100 for its own use. ** A [file control opcodes | list of opcodes] less than 100 is available. ** Applications that define a custom xFileControl method should use opcodes ** greater than 100 to avoid conflicts. VFS implementations should ** return [SQLITE_NOTFOUND] for file control opcodes that they do not ** recognize. *** ** The xSectorSize() method returns the sector size of the ** device that underlies the file. The sector size is the ** minimum write that can be performed without disturbing ** other bytes in the file. The xDeviceCharacteristics() ** method returns a bit vector describing behaviors of the ** underlying device: *** ** [SQLITE_IOCAP_ATOMIC] ** [SQLITE_IOCAP_ATOMIC512] ** [SQLITE_IOCAP_ATOMIC1K] ** [SQLITE_IOCAP_ATOMIC2K] ** [SQLITE_IOCAP_ATOMIC4K] ** [SQLITE_IOCAP_ATOMIC8K] ** [SQLITE_IOCAP_ATOMIC16K] ** [SQLITE_IOCAP_ATOMIC32K] ** [SQLITE_IOCAP_ATOMIC64K] ** [SQLITE_IOCAP_SAFE_APPEND] ** [SQLITE_IOCAP_SEQUENTIAL] ** [SQLITE_IOCAP_UNDELETABLE_WHEN_OPEN] ** [SQLITE_IOCAP_POWERSAFE_OVERWRITE] ** [SQLITE_IOCAP_IMMUTABLE] ** ** ** The SQLITE_IOCAP_ATOMIC property means that all writes of ** any size are atomic. The SQLITE_IOCAP_ATOMICCnnn values ** mean that writes of blocks that are nnn bytes in size and ** are aligned to an address which is an integer multiple of ** nnn are atomic. The SQLITE_IOCAP_SAFE_APPEND value means ** that when data is appended to a file, the data is appended ** first then the size of the file is extended, never the other ** way around. The SQLITE_IOCAP_SEQUENTIAL property means that ** information is written to disk in the same order as calls ** to xWrite(). ** ** If xRead() returns SQLITE_IOERR_SHORT_READ it must also fill ** in the unread portions of the buffer with zeros. A VFS that ** fails to zero-fill short reads might seem to work. However, ** failure to zero-fill short reads will eventually lead to ** database corruption.

61974. if i==0 and iCol==0, then record pRec is smaller than all samples ** in the aSample[] array. Otherwise, if (iCol>0) then pRec must ** be greater than or equal to the (iCol) field prefix of sample i. ** If (i>0), then pRec must also be greater than sample (i-1).
61975. ** The block of page numbers associated with the first hash-table in a ** wal-index is smaller than usual. This is so that there is a complete ** hash-table on each aligned 32KB page of the wal-index.
61976. **comment:** ** This function is used by the implementation of the IN (...) operator. ** The pX parameter is the expression on the RHS of the IN operator, which ** might be either a list of expressions or a subquery. ** ** The job of this routine is to find or create a b-tree object that can ** be used either to test for membership in the RHS set or to iterate through ** all members of the RHS set, skipping duplicates. ** ** A cursor is opened on the b-tree object that is the RHS of the IN operator ** and pX->iTable is set to the index of that cursor. ** ** The returned value of this function indicates the b-tree type, as follows: ** **
IN_INDEX_ROWID - The cursor was opened on a database table. ** IN_INDEX_INDEX_ASC - The cursor was opened on an ascending index. **
IN_INDEX_INDEX_DESC - The cursor was opened on a descending index. ** IN_INDEX_EPH - The cursor was opened on a specially created and ** populated ephemeral table. ** IN_INDEX_NOOP - No cursor was allocated. The IN operator must be ** implemented as a sequence of comparisons. ** ** An existing b-tree might be used if the RHS expression pX is a simple ** subquery such as: ** ** SELECT <column1>, <column2>... FROM <table> ** ** If the RHS of the IN operator is a list or a more complex subquery, then ** an ephemeral table might need to be generated from the RHS and then ** pX->iTable made to point to the ephemeral table instead of an ** existing table. ** ** The inFlags parameter must contain exactly one of the bits ** IN_INDEX_MEMBERSHIP or IN_INDEX_LOOP. If inFlags contains ** IN_INDEX_MEMBERSHIP, then the generated table will be used for a ** fast membership test. When the IN_INDEX_LOOP bit is set, the ** IN index will be used to loop over all values of the RHS of the ** IN operator. ** ** When IN_INDEX_LOOP is used (and the b-tree will be used to iterate ** through the set members) then the b-tree must not contain duplicates. ** An ephemeral table must be used unless the selected columns are guaranteed ** to be unique - either because it is an INTEGER PRIMARY KEY or due to ** a UNIQUE constraint or index. ** ** When IN_INDEX_MEMBERSHIP is used (and the b-tree will be used ** for fast set membership tests) then an ephemeral table must ** be used unless <columns> is a single INTEGER PRIMARY KEY column or an ** index can be found with the specified <columns> as its left-most. ** ** If the IN_INDEX_NOOP and IN_INDEX_MEMBERSHIP are both set and ** if the RHS of the IN operator is a list (not a subquery) then this ** routine might decide that creating an ephemeral b-tree for membership ** testing is too expensive and return IN_INDEX_NOOP. In that case, the ** calling routine should implement the IN operator using a sequence ** of Eq or Ne comparison operations. ** ** When the b-tree is being used for membership tests, the calling function ** might need to know whether or not the RHS side of the IN operator ** contains a NULL. If prRhsHasNull is not a NULL pointer and ** if there is any chance that the (...) might contain a NULL value at ** runtime, then a register is allocated and the register number written ** to *prRhsHasNull. If there is no chance that the (...) contains a ** NULL value, then *prRhsHasNull is left unchanged. ** ** If a register is allocated and its location stored in *prRhsHasNull, then ** the value in that register will be NULL if the b-tree contains one or more ** NULL values, and it will be some non-NUL value if the b-tree contains no ** NULL values. ** ** If the aiMap parameter is not NULL, it must point to an array containing ** one element for each column returned by the SELECT statement on the RHS ** of the IN(...) operator. The i'th entry of the array is populated with the ** offset of the index column that matches the i'th column returned by the ** SELECT. For example, if the expression and selected index are: ** ** (?, ?, ?) IN (SELECT a, b, c FROM t1) ** CREATE INDEX i1 ON t1(b, c, a); ** ** then aiMap[] is populated with {2, 0, 1}.

62043. Pointer to a prior allocation
62044. Base register where results are written
62045. Handle pointing to row containing value
62046. Grow the hash table if required
62047. Table associated with change
62048. ** Maximum error message length (in chars) for WinRT.
62049. zNum is empty or contains non-numeric text or is longer ** than 19 digits (thus guaranteeing that it is too large)
62050. Value to return if (rhs < lhs)
62051. Opcode: Divide P1 P2 P3 * * * Synopsis: r[P3]=r[P2]/r[P1] ** ** Divide the value in register P1 by the value in register P2 ** and store the result in register P3 (P3=P2/P1). If the value in ** register P1 is zero, then the result is NULL. If either input is ** NULL, the result is NULL.
62052. 326
62053. ** Obtain permyriadage (permyriadage is to 10000 as percentage is to 100) ** progress indications for the two stages of an RBU update. This API may ** be useful for driving GUI progress indicators and similar. ** ** An RBU update is divided into two stages: ** ** Stage 1, in which changes are accumulated in an oal/wal file, and ** ** Stage 2, in which the contents of the wal file are copied into the ** main database. ** ** The update is visible to non-RBU clients during stage 2. During stage 1 ** non-RBU reader clients may see the original database. ** ** If this API is called during stage 2 of the update, output variable ** (*pnOne) is set to 10000 to indicate that stage 1 has finished and (*pnTwo) ** to a value between 0 and 10000 to indicate the permyriadage progress of ** stage 2. A value of 5000 indicates that stage 2 is half finished, ** 9000 indicates that it is 90% finished, and so on. ** ** If this API is called during stage 1 of the update, output variable ** (*pnTwo) is set to 0 to indicate that stage 2 has not yet started. The ** value to which (*pnOne) is set depends on whether or not the RBU ** database contains an "rbu_count" table. The rbu_count table, if it ** exists, must contain the same columns as the following: ** ** CREATE TABLE rbu_count(tbl TEXT PRIMARY KEY, cnt INTEGER) WITHOUT ROWID; ** ** There must be one row in the table for each source (data_xxx) table within ** the RBU database. The 'tbl' column should contain the name of the source ** table. The 'cnt' column should contain the number of rows within the ** source table. ** ** If the rbu_count table is present and populated correctly and this ** API is called during stage 1, the *pnOne output variable is set to the ** permyriadage progress of the same stage. If the rbu_count table does ** not exist, then (*pnOne) is set to -1 during stage 1. If the rbu_count ** table exists but is not correctly populated, the value of the *pnOne ** output variable during stage 1 is undefined.
62054. Maximum number of entries in hash table before ** sub-dividing and re-hashing.
62055. IMPLEMENTATION-OF: R-20790-14025 The sqlite3_threadsafe() function returns ** zero if and only if SQLite was compiled with mutexing code omitted due to ** the SQLITE_THREADSAFE compile-time option being set to 0.
62056. **comment:** If the file was just truncated to a size smaller than the currently ** mapped region, reduce the effective mapping size as well. SQLite will ** use read() and write() to access data beyond this point from now on.

62129. **comment:** ** CAPI3REF: Convenience Routines For Running Queries ** METHOD: sqlite3 *** This is a legacy interface that is preserved for backwards compatibility. ** Use of this interface is not recommended. *** Definition: A result table is memory data structure created by the ** [sqlite3_get_table()] interface. A result table records the ** complete query results from one or more queries. *** The table conceptually has a number of rows and columns. But ** these numbers are not part of the result table itself. These ** numbers are obtained separately. Let N be the number of rows ** and M be the number of columns. *** A result table is an array of pointers to zero-terminated UTF-8 strings. ** There are (N+1)*M elements in the array. The first M pointers point ** to zero-terminated strings that contain the names of the columns. ** The remaining entries all point to query results. NULL values result ** in NULL pointers. All other values are in their UTF-8 zero-terminated ** string representation as returned by [sqlite3_column_text()]. *** A result table might consist of one or more memory allocations. ** It is not safe to pass a result table directly to [sqlite3_free()]. ** A result table should be deallocated using [sqlite3_free_table()]. *** ^As an example of the result table format, suppose a query result ** is as follows: *** <blockquote><pre> ** Name | Age ** ----- ** Alice | 43 ** Bob | 28 ** Cindy | 21 ** </pre></blockquote> *** There are two column (M==2) and three rows (N==3). Thus the ** result table has 8 entries. Suppose the result table is stored ** in an array names azResult. Then azResult holds this content: *** <blockquote><pre> ** azResult[91;0] = "Name"; ** azResult[91;1] = "Age"; ** azResult[91;2] = "Alice"; ** azResult[91;3] = "43"; ** azResult[91;4] = "Bob"; ** azResult[91;5] = "28"; ** azResult[91;6] = "Cindy"; ** azResult[91;7] = "21"; ** </pre></blockquote> *** ^The sqlite3_get_table() function evaluates one or more ** semicolon-separated SQL statements in the zero-terminated UTF-8 ** string of its 2nd parameter and returns a result table to the ** pointer given in its 3rd parameter. *** After the application has finished with the result from sqlite3_get_table(), ** it must pass the result table pointer to sqlite3_free_table() in order to ** release the memory that was malloced. Because of the way the ** [sqlite3_malloc()] happens within sqlite3_get_table(), the calling ** function must not try to call [sqlite3_free()] directly. Only ** [sqlite3_free_table()] is able to release the memory properly and safely. *** The sqlite3_get_table() interface is implemented as a wrapper around ** [sqlite3_exec()]. The sqlite3_get_table() routine does not have access ** to any internal data structures of SQLite. It uses only the public ** interface defined here. As a consequence, errors that occur in the ** wrapper layer outside of the internal [sqlite3_exec()] call are not ** reflected in subsequent calls to [sqlite3_errcode()] or ** [sqlite3_errmsg()].

label: code-design

62130. Convert the OP_CreateTable opcode that would normally create the ** root-page for the table into an OP_CreateIndex opcode. The index ** created will become the PRIMARY KEY index.

62131. Take care here not to generate a TK_VECTOR containing only a ** single value. Since the parser never creates such a vector, some ** of the subroutines do not handle this case.

Otherwise, SQLITE_OK. ** ** If there are outstanding FK violations and this function returns ** SQLITE_ERROR, set the result of the VM to SQLITE_CONSTRAINT_FOREIGNKEY ** and write an error message to it. Then return SQLITE_ERROR.

62215. ** The sqlite3_mutex.id, sqlite3_mutex.nRef, and sqlite3_mutex.owner fields ** are necessary under two conditions: (1) Debug builds and (2) using ** home-grown mutexes. Encapsulate these conditions into a single #define.

62216. ** Return an Expr object that refers to column iCol of table pTab which ** has cursor iCur.

62217. Colset to filter on

62218. ** Sort the linked list of records headed at pTask->pList. Return ** SQLITE_OK if successful, or an SQLite error code (i.e. SQLITE_NOMEM) if ** an error occurs.

62219. Store the token that zCsr points to in tname.

62220. We explicitly don't support UTF-8 delimiters for now.

62221. using_opt ::= USING LP idlist RP

62222. ** If parameter iOp is less than zero, then invoke the destructor for ** all auxiliary data pointers currently cached by the VM passed as ** the first argument. ** ** Or, if iOp is greater than or equal to zero, then the destructor is ** only invoked for those auxiliary data pointers created by the user ** function invoked by the OP_Function opcode at instruction iOp of ** VM pVdbe, and only then if: ** ** * the associated function parameter is the 32nd or later (counting ** from left to right), or ** ** * the corresponding bit in argument mask is clear (where the first ** function parameter corresponds to bit 0 etc.).

62223. ** Set or retrieve the codec for this pager

62224. Forward Declaration

62225. Shared memory segment information

62226. EVIDENCE-OF: R-15465-20813 The maximum and minimum embedded payload ** fractions and the leaf payload fraction values must be 64, 32, and 32. ** ** The original design allowed these amounts to vary, but as of ** version 3.6.0, we require them to be fixed.

62227. When the NATURAL keyword is present, add WHERE clause terms for ** every column that the two tables have in common.

62228. Test to make sure the linear array exactly matches the ** Bitvec object. Start with the assumption that they do ** match (rc==0). Change rc to non-zero if a discrepancy ** is found.

62229. ** A memory allocation (also called a "chunk") consists of two or ** more blocks where each block is 8 bytes. The first 8 bytes are ** a header that is not returned to the user. ** ** A chunk is two or more blocks that is either checked out or ** free. The first block has format u.hdr. u.hdr.size4x is 4 times the ** size of the allocation in blocks if the allocation is free. ** The u.hdr.size4x&1 bit is true if the chunk is checked out and ** false if the chunk is on the freelist. The u.hdr.size4x&2 bit ** is true if the previous chunk is checked out and false if the ** previous chunk is free. The u.hdr.prevSize field is the size of ** the previous chunk in blocks if the previous chunk is on the ** freelist. If the previous chunk is checked out, then ** u.hdr.prevSize can be part of the data for that chunk and should ** not be read or written. ** ** We often identify a chunk by its index in mem3.aPool[]. When ** this is done, the chunk index refers to the second block of ** the chunk. In this way, the first chunk has an index of 1. ** A chunk index of 0 means "no such chunk" and is the equivalent ** of a NULL pointer. ** ** The second block of free chunks is of the form u.list. The ** two fields form a double-linked list of chunks of related sizes. ** Pointers to the head of the list are stored in mem3.aiSmall[] ** for smaller chunks and mem3.aiHash[] for larger chunks. ** ** The second block of a chunk is user data if the chunk is checked ** out. If a chunk is checked out, the user data may extend into ** the u.hdr.prevSize value of the following chunk.

62230. ** This is a copy of the sqlite3GetVarint32() routine from the SQLite core. ** Except, this version does handle the single byte case that the core ** version depends on being handled before its function is called.

62231. ** Change the value of the P4 operand for a specific instruction. ** This routine is useful when a large program is loaded from a ** static array using sqlite3VdbeAddOpList but we want to make a ** few minor changes to the program. ** ** If n>=0 then the P4 operand is dynamic, meaning that a copy of ** the

string is made into memory obtained from sqlite3_malloc(). ** A value of n==0 means copy bytes of zP4 up to and including the ** first null byte. If n>0 then copy n+1 bytes of zP4. *** Other values of n (P4_STATIC, P4_COLLSEQ etc.) indicate that zP4 points ** to a string or structure that is guaranteed to exist for the lifetime of ** the Vdbe. In these cases we can just copy the pointer. *** If addr<0 then change P4 on the most recently inserted instruction.

62232. sqlite3PageMalloc()

62233. Memory location that acts as accumulator

62234. pPage might not be a btree page; it might be an overflow page ** or ptrmap page or a free page. In those cases, the following ** call to btreeInitPage() will likely return SQLITE_CORRUPT. ** But no harm is done by this. And it is very important that ** btreeInitPage() be called on every btree page so we make ** the call for every page that comes in for re-initing.

62235. Size each output buffer in bytes

62236. Number of retries

62237. OUT: Score

62238. Allocate the iterator

62239. ** This function is an optimized version of sqlite3VdbeRecordCompare() ** that (a) the first field of pPKey2 is a string, that (b) the first field ** uses the collation sequence BINARY and (c) that the size-of-header varint ** at the start of (pKey1/nKey1) fits in a single byte.

62240. dbnm ::= DOT nm

62241. s: p0<<21 | p1<<14 | p2<<7 | p3 (masked)

62242. If an error occurred in findInodeInfo(), close the file descriptor ** immediately, before releasing the mutex. findInodeInfo() may fail ** in two scenarios: ** ** (a) A call to fstat() failed. ** (b) A malloc failed. *** Scenario (b) may only occur if the process is holding no other ** file descriptors open on the same file. If there were other file ** descriptors on this file, then no malloc would be required by ** findInodeInfo(). If this is the case, it is quite safe to close ** handle h - as it is guaranteed that no posix locks will be released ** by doing so. *** ** If scenario (a) caused the error then things are not so safe. The ** implicit assumption here is that if fstat() fails, things are in ** such bad shape that dropping a lock or two doesn't matter much.

62243. 860

62244. If all the following are true: ** ** 1) this is a read operation, and ** 2) data is required from the start of this overflow page, and ** 3) there is no open write-transaction, and ** 4) the database is file-backed, and ** 5) the page is not in the WAL file ** 6) at least 4 bytes have already been read into the output buffer ** ** then data can be read directly from the database file into the ** output buffer, bypassing the page-cache altogether. This speeds ** up loading large records that span many overflow pages.

62245. ** Add the file descriptor used by file handle pFile to the corresponding ** pUnused list.

62246. New cursor object

62247. Filename might have query parameters

62248. The minimum PMA size is set to this value multiplied by the database ** page size in bytes.

62249. idlist_opt

62250. **comment:** ** Copy the contents of sample *pNew into the p->a[] array. If necessary, ** remove the least desirable sample from p->a[] to make room.

label: code-design

62594. Value for "from" column of output
62595. ** The SELECT statement iterating through the keys for the current object ** (p->objiter.pSelect) currently points to a valid row. However, there ** is something wrong with the rru_control value in the rru_control value ** stored in the (p->nCol+1)'th column. Set the error code and error message ** of the RBU handle to something reflecting this.
62596. ** If SQLITE_ENABLE_8_3_NAMES is set at compile-time and if the database ** filename in zBaseFilename is a URI with the "8_3_names=1" parameter and ** if filename in z[] has a suffix (a.k.a. "extension") that is longer than ** three characters, then shorten the suffix on z[] to be the last three ** characters of the original suffix. *** If SQLITE_ENABLE_8_3_NAMES is set to 2 at compile-time, then always ** do the suffix shortening regardless of URI parameter. *** Examples: *** test.db-journal => test.nal ** test.db-wal => test.wal ** test.db-shm => test.shm ** test.db-mj7f3319fa => test.9fa
62597. A small processing code
62598. ** This function gathers 'y' or 'b' data for a single phrase.
62599. Return from sqlite3WhereBegin()
62600. Neither side of the comparison is a column. Compare the ** results directly.
62601. Largest allocation (exclusive of internal frag)
62602. A column number within table iCur
62603. True if auto-vacuum is enabled
62604. WHERE clause information
62605. The string collected so far
62606. ** Write an error message into *pzErr
62607. Opcode: DropIndex P1 * * P4 * * * Remove the internal (in-memory) data structures that describe ** the index named P4 in database P1. This is called after an index ** is dropped from disk (using the Destroy opcode) ** in order to keep the internal representation of the ** schema consistent with what is on disk.
62608. Index of first cell to add
62609. Append the data to the string buffer.
62610. Text of the SQL statement that generated this
62611. ** Apply a delta. *** The output buffer should be big enough to hold the whole output ** file and a NUL terminator at the end. The delta_output_size() ** routine will determine this size for you. *** The delta string should be null-terminated. But the delta string ** may contain embedded NUL characters (if the input and output are ** binary files) so we also have to pass in the length of the delta in ** the lenDelta parameter. *** This function returns the size of the output file in bytes (excluding ** the final NUL terminator character). Except, if the delta string is ** malformed or intended for use with a source file other than zSrc, ** then this routine returns -1. *** Refer to the delta_create() documentation above for a description ** of the delta file format.
62612. Number of columns in the PRIMARY KEY
62613. struct Trigger
62614. Only one of WHERE_OR_SUBCLAUSE or WHERE_USE_LIMIT
62615. Temporarily holds the number of cursors assigned
62616. zero or more BTCL_* flags defined below
62617. Page 1 is always available in cache, because ** pCache->nRefSum>0
62618. ** Maximum size (in Mem3Blocks) of a "small" chunk.

62619. ** The "file format" number is an integer that is incremented whenever ** the VDBE-level file format changes. The following macros define the ** the default file format for new databases and the maximum file format ** that the library can read.

62620. Text inserted into table-name column

62621. Default locking-mode for attached dbs

62622. OS Interface

62623. The right-hand side of the AS subexpression

62624. Buffer containing segment interior node

62625. (285) columnlist ::= columnname carglist

62626. Unsorted entry count

62627. IMP: R-51463-25634

62628. Begin scanning through the ephemeral table.

62629. Create the new column data

62630. **comment:** Opcode: Goto * P2 *** *** An unconditional jump to address P2. ** The next instruction executed will be ** the one at index P2 from the beginning of ** the program. *** ** The P1 parameter is not actually used by this opcode. However, it ** is sometimes set to 1 instead of 0 as a hint to the command-line shell ** that this Goto is the bottom of a loop and that the lines from P2 down ** to the current line should be indented for EXPLAIN output.

label: code-design

62631. SQLITE_CORE || SQLITE_ENABLE_FTS3

62632. Update the Fts5Structure. It is written back to the database by the ** fts5StructureRelease() call below.

62633. No usable constraint

62634. Is a label of an object

62635. ** Free a hash table object.

62636. Current block id

62637. If input table has column "rbu_rowid"

62638. A-overwrites-X

62639. **comment:** ** This function is used after merging multiple segments into a single large ** segment to delete the old, now redundant, segment b-trees. Specifically, ** it: *** *** 1) Deletes all %_segments entries for the segments associated with ** each of the SegReader objects in the array passed as the third ** argument, and ** *** 2) deletes all %_segdir entries with level iLevel, or all %_segdir ** entries regardless of level if (iLevel<0). *** ** SQLITE_OK is returned if successful, otherwise an SQLite error code.

label: code-design

62640. ** Somewhere on pPage is a pointer to page iFrom. Modify this pointer so ** that it points to iTo. Parameter eType describes the type of pointer to ** be modified, as follows: *** PTRMAP_BTREE: pPage is a btree-page. The pointer points at a child ** page of pPage. *** PTRMAP_OVERFLOW1: pPage is a btree-page. The pointer points at an overflow ** page pointed to by one of the cells on pPage. *** PTRMAP_OVERFLOW2: pPage is an overflow-page. The pointer points at the next ** overflow page in the list.

62641. ** Compare the entries pointed to by two Fts3SegReader structures. ** Comparison is as follows: *** ** 1) EOF is greater than not EOF. *** ** 2) The current terms (if any) are compared using memcmp(). If one ** term is a prefix of another, the longer term is considered the ** larger. *** ** 3) By segment age. An older segment is considered larger.

62642. **comment:** ** CAPI3REF: Result Values From A Query ** KEYWORDS: {column access functions} ** METHOD: sqlite3_stmt *** *** Summary: ** <blockquote><table border=0 cellpadding=0 cellspacing=0> ** <tr><td>sqlite3_column_blob</td>→<td>BLOB result ** <tr><td> sqlite3_column_double</td>→<td>REAL result ** <tr><td>sqlite3_column_int</td>→<td>32-bit INTEGER result ** <tr><td> sqlite3_column_int64</td>→<td>64-bit INTEGER result ** <tr><td>sqlite3_column_text</td>→<td>UTF-8 TEXT result ** <tr><td> sqlite3_column_text16</td>→<td>UTF-16 TEXT result ** <tr><td>sqlite3_column_value</td>→<td>The result as an ** [sqlite3_value|unprotected sqlite3_value] object. ** <tr><td> </td> <td> </td>→<td>Size of a BLOB ** or a UTF-8 TEXT result in bytes ** <tr><td>sqlite3_column_bytes16 </td> </td>→<td>Size of UTF-16 ** TEXT in bytes ** <tr><td>sqlite3_column_type</td>→<td>Default ** datatype of the result ** </table></blockquote> *** *** Details: *** ^These routines return information about a single column of the current ** result row of a query. ^In every case the first argument is a pointer ** to the [prepared statement] that is being evaluated (the [sqlite3_stmt*] ** that was returned from [sqlite3_prepare_v2()] or one of its variants) ** and the second argument is the index of the column for which information ** should be returned. ^The leftmost column of the result set has the index 0. ** ^The number of columns in the result can be determined using ** [sqlite3_column_count()]. *** ** If the SQL statement does not currently point to a valid row, or if the ** column index is out of range, the result is undefined. ** These routines may only be called when the most recent call to ** [sqlite3_step()] has returned [SQLITE_ROW] and neither ** [sqlite3_reset()] nor [sqlite3_finalize()] have been called subsequently. ** If any of these routines are called after [sqlite3_reset()] or ** [sqlite3_finalize()] or after [sqlite3_step()] has returned ** something other than [SQLITE_ROW], the results are undefined. ** If [sqlite3_step()] or [sqlite3_reset()] or [sqlite3_finalize()] ** are called from a different thread while any of these routines ** are pending, then the results are undefined. *** ** The first six interfaces (_blob, _double, _int, _int64, _text, and _text16) ** each return the value of a result column in a specific data format. If ** the result column is not initially in the requested format (for example, ** if the query returns an integer but the sqlite3_column_text() interface ** is used to extract the value) then an automatic type conversion is performed. *** ** ^The sqlite3_column_type() routine returns the ** [SQLITE_INTEGER | datatype code] for the initial data type ** of the result column. ^The returned value is one of [SQLITE_INTEGER], ** [SQLITE_FLOAT], [SQLITE_TEXT], [SQLITE_BLOB], or [SQLITE_NULL]. ** The return value of sqlite3_column_type() can be used to decide which ** of the first six interface should be used to extract the column value. ** The value returned by sqlite3_column_type() is only meaningful if no ** automatic type conversions have occurred for the value in question. ** After a type conversion, the result of calling sqlite3_column_type() ** is undefined, though harmless. Future ** versions of SQLite may change the behavior of sqlite3_column_type() ** following a type conversion. *** ** If the result is a BLOB or a TEXT string, then the sqlite3_column_bytes() ** or sqlite3_column_bytes16() interfaces can be used to determine the size ** of that BLOB or string. *** ** ^If the result is a BLOB or UTF-8 string then the sqlite3_column_bytes() ** routine returns the number of bytes in that BLOB or string. ** ^If the result is a UTF-16 string, then sqlite3_column_bytes() converts ** the string to UTF-8 and then returns the number of bytes. ** ^If the result is a numeric value then sqlite3_column_bytes() uses ** [sqlite3_snprintf()] to convert that value to a UTF-8 string and returns ** the number of bytes in that string. ** ^If the result is NULL, then sqlite3_column_bytes() returns zero. ** ** ^If the result is a BLOB or UTF-16 string then the sqlite3_column_bytes16() ** routine returns the number of bytes in that BLOB or string. ** ^If the result is a UTF-8 string, then sqlite3_column_bytes16() converts ** the string to UTF-16 and then returns the number of bytes. ** ^If the result is a numeric value then sqlite3_column_bytes16() uses ** [sqlite3_snprintf()] to convert that value to a UTF-16 string and returns ** the number of bytes in that string. ** ^If the result is NULL, then sqlite3_column_bytes16() returns zero. ** ** ^The values returned by [sqlite3_column_bytes()] and ** [sqlite3_column_bytes16()] do not include the zero terminators at the end ** of the string. ^For clarity: the values returned by ** [sqlite3_column_bytes()] and [sqlite3_column_bytes16()] are the number of ** bytes in the string, not the number of characters. *** ** ^Strings returned by sqlite3_column_text() and sqlite3_column_text16(), ** even empty strings, are always zero-terminated. ^The return ** value from sqlite3_column_blob() for a zero-length BLOB is a NULL pointer. ** ** Warning: ^The object returned by [sqlite3_column_value()] is an ** [unprotected sqlite3_value] object. In a multithreaded environment, ** an unprotected sqlite3_value object may only be used safely with ** [sqlite3_bind_value()] and [sqlite3_result_value()]. ** If the [unprotected sqlite3_value] object returned by ** [sqlite3_column_value()] is used in any other way, including calls ** to routines like [sqlite3_value_int()], [sqlite3_value_text()], ** or [sqlite3_value_bytes()], the behavior is not threadsafe. ** Hence, the sqlite3_column_value() interface ** is normally only useful within the implementation of ** [application-defined SQL functions] or [virtual tables], not within ** top-level application code. *** ** The these routines may attempt to convert the datatype of the result. ** ^For example, if the internal representation is FLOAT and a text result ** is requested, [sqlite3_snprintf()] is used internally to perform the ** conversion automatically. ^The following table details the conversions ** that are applied: *** *** <blockquote> ** <table border="1"> ** <tr><th> Internal
 Type <th> Requested
 Type <th> Conversion *** *** <tr><td> NULL </td> INTEGER </td> Result is 0 ** <tr><td> NULL </td> <td> FLOAT </td> Result is 0.0 ** <tr><td> NULL </td> TEXT </td> Result is a NULL pointer ** <tr><td> NULL </td> BLOB </td> Result is a NULL pointer ** <tr><td> INTEGER </td> FLOAT </td> Convert from integer to float ** <tr><td> INTEGER </td> TEXT </td> ASCII rendering of the integer ** <tr><td> INTEGER </td> BLOB </td> Same as INTEGER->TEXT ** <tr><td> FLOAT </td> INTEGER </td> [CAST] to INTEGER ** <tr><td> FLOAT </td> TEXT </td> ASCII rendering of the float ** <tr><td> FLOAT </td> BLOB </td> [CAST] to BLOB ** <tr><td> TEXT </td> INTEGER </td> [CAST] to INTEGER ** <tr><td> TEXT </td> REAL ** <tr><td> TEXT </td> BLOB </td> No change ** <tr><td> BLOB </td> INTEGER </td> [CAST] to INTEGER ** <tr><td> BLOB </td> FLOAT </td> [CAST] to REAL ** <tr><td> BLOB </td> TEXT </td> Add a zero terminator if needed ** </table> ** </blockquote> /*** Note that when type conversions occur, pointers returned by prior ** calls to sqlite3_column_blob(), sqlite3_column_text(), and/or ** sqlite3_column_text16() may be invalidated. ** Type conversions and pointer invalidations might occur ** in the following cases: *** *** ** The initial content is a BLOB and sqlite3_column_text() or ** sqlite3_column_text16() is called. A zero-terminator might ** need to be added to the string. ** The initial content is UTF-8 text and sqlite3_column_bytes16() or ** sqlite3_column_text16() is called. The content must be converted ** to UTF-16. ** The initial content is UTF-

16 text and sqlite3_column_bytes() or ** sqlite3_column_text() is called. The content must be converted ** to UTF-8. ** *** ^Conversions between UTF-16be and UTF-16le are always done in place and do ** not invalidate a prior pointer, though of course the content of the buffer ** that the prior pointer references will have been modified. Other kinds ** of conversion are done in place when it is possible, but sometimes they ** are not possible and in those cases prior pointers are invalidated. *** ^The safest policy is to invoke these routines ** in one of the following ways: *** ** sqlite3_column_text() followed by sqlite3_column_bytes() ** sqlite3_column_blob() followed by sqlite3_column_bytes() ** sqlite3_column_text16() followed by sqlite3_column_bytes16() ** *** In other words, you should call sqlite3_column_text(), ** sqlite3_column_blob(), or sqlite3_column_text16() first to force the result ** into the desired format, then invoke sqlite3_column_bytes() or ** sqlite3_column_bytes16() to find the size of the result. Do not mix calls ** to sqlite3_column_text() or sqlite3_column_blob() with calls to ** sqlite3_column_bytes16(), and do not mix calls to sqlite3_column_text16() ** with calls to sqlite3_column_bytes(). *** ^The pointers returned are valid until a type conversion occurs as ** described above, or until [sqlite3_step()] or [sqlite3_reset()] or ** [sqlite3_finalize()] is called. ^The memory space used to hold strings ** and BLOBs is freed automatically. Do not pass the pointers returned ** from [sqlite3_column_blob()], [sqlite3_column_text()], etc. into ** [sqlite3_free()]. *** ^If a memory allocation error occurs during the evaluation of any ** of these routines, a default value is returned. The default value ** is either the integer 0, the floating point number 0.0, or a NULL ** pointer. Subsequent calls to [sqlite3_errcode()] will return ** [SQLITE_NOMEM].^

62650. The index of the cell within the node

62651. 890

62652. Next select to the left in a compound

62653. TUNING: One-time cost for computing the automatic index is ** estimated to be X*N*log2(N) where N is the number of rows in ** the table being indexed and where X is 7 (LogEst=28) for normal ** tables or 1.375 (LogEst=4) for views and subqueries. The value ** of X is smaller for views and subqueries so that the query planner ** will be more aggressive about generating automatic indexes for ** those objects, since there is no opportunity to add schema ** indexes on subqueries and views.

62654. ** The following global variable is incremented whenever the ** transfer optimization is used. This is used for testing ** purposes only - to make sure the transfer optimization really ** is happening when it is supposed to.

62655. Second part of the name of the table or view

62656. Leave error message here

62657. ** This function is called when an UPDATE or DELETE operation is being ** compiled on table pTab, which is the parent table of foreign-key pFKey. ** If the current operation is an UPDATE, then the pChanges parameter is ** passed a pointer to the list of columns being modified. If it is a ** DELETE, pChanges is passed a NULL pointer. *** ^It returns a pointer to a Trigger structure containing a trigger ** equivalent to the ON UPDATE or ON DELETE action specified by pFKey. ** If the action is "NO ACTION" or "RESTRICT", then a NULL pointer is ** returned (these actions require no special handling by the triggers ** subsystem, code for them is created by fkScanChildren()). *** ^For example, if pFKey is the foreign key and pTab is table "p" in ** the following schema: *** ^CREATE TABLE p(pk PRIMARY KEY); ** ^CREATE TABLE c(ck REFERENCES p ON DELETE CASCADE); *** ^then the returned trigger structure is equivalent to: *** ^CREATE TRIGGER ... DELETE ON p BEGIN ** DELETE FROM c WHERE ck = old.pk; ** END; *** ^The returned pointer is cached as part of the foreign key object. It ** is eventually freed along with the rest of the foreign key object by ** sqlite3FkDelete().

62658. Figure out if we have any triggers and if the table being ** deleted from is a view

62659. ** Reset the aggregate accumulator. ** ^The aggregate accumulator is a set of memory cells that hold ** intermediate results while calculating an aggregate. This ** routine generates code that stores NULLs in all of those memory ** cells.

62660. Wal-index header for current transaction

62661. ** sqlite3_test_control(FAULT_INSTALL, xCallback) *** ^Arrange to invoke xCallback() whenever sqlite3FaultSim() is called, ** if xCallback is not NULL. ** ^As a test of the fault simulator mechanism itself, sqlite3FaultSim(0) ** is called immediately after installing the new callback and the return ** value from sqlite3FaultSim(0) becomes the return from ** sqlite3_test_control().

62662. Column number of the index

62663. **comment:** PmaReaders should be normally initialized in order, as if they are ** reading from the same temp file this makes for more linear file IO. ** However, in the INCRINIT_ROOT case, if PmaReader aReadr[nTask-1] is ** in use it will block the vdbePmaReaderNext() call while it uses ** the main thread to fill its buffer. So calling PmaReaderNext() ** on this PmaReader before any of the multi-threaded PmaReaders takes ** better advantage of multi-processor hardware.

label: code-design

62664. Make sure there are enough memory cells allocated to accommodate ** the regPrev array and a trailing rowid (the rowid slot is required ** when building a record to insert into the sample column of ** the sqlite_stat4 table).

62665. ** This function is used to read a single varint from a buffer. Parameter ** pEnd points 1 byte past the end of the buffer. When this function is ** called, if *pp points to pEnd or greater, then the end of the buffer ** has been reached. In this case *pp is set to 0 and the function returns. *** ^If *pp does not point to or past pEnd, then a single varint is read ** from *pp. *pp is then set to point 1 byte past the end of the read varint. *** ^If bDescIdx is false, the value read is added to *pVal before returning. ** If it is true, the value read is subtracted from *pVal before this ** function returns.

62666. Strategy index

62667. This is the case if the data for the INSERT is coming from a ** single-row VALUES clause

62668. Delete the %_content record

62669. **comment:** The first time a column affinity string for a particular index is ** required, it is allocated and populated here. It is then stored as ** a member of the Index structure for subsequent use. *** ^The column affinity string will eventually be deleted by ** sqliteDeleteIndex() when the Index structure itself is cleaned ** up.

label: code-design

62670. ** Let any sequence of one or more vowels be represented by V and let ** C be sequence of one or more consonants. Then every word can be ** represented as: *** ^[C] (VC){m} [V] *** ^In prose: A word is an optional consonant followed by zero or ** vowel-consonant pairs followed by an optional vowel. "m" is the ** number of vowel consonant pairs. This routine computes the value ** of m for the first i bytes of a word. *** ^Return true if the m-value for z is 1 or more. In other words, ** return true if z contains at least one vowel that is followed ** by a consonant. *** ^In this routine z[] is in reverse order. So we are really looking ** for an instance of a consonant followed by a vowel.

62671. return true if number and no extra non-whitespace characters after

62709. The object to be destroyed
62710. ** Create a new sqlite3_value object, containing the value of pExpr. *** This only works for very simple expressions that consist of one constant ** token (i.e. "5", "5.1", "a string"). If the expression can ** be converted directly into a value, then the value is allocated and ** a pointer written to *ppVal. The caller is responsible for deallocating ** the value by passing it to sqlite3ValueFree() later on. If the expression ** cannot be converted to a value, then *ppVal is set to NULL.
62711. Free the connection p
62712. Instead of invoking the conflict handler, append the change blob ** to the SessionApplyCtx.constraints buffer.
62713. ** Return UTF-8 encoded English language explanation of the most recent ** error.
62714. **comment:** ** The replace() function. Three arguments are all strings: call ** them A, B, and C. The result is also a string which is derived ** from A by replacing every occurrence of B with C. The match ** must be exact. Collating sequences are not used.
label: code-design
62715. ** Release a reference to data record returned by an earlier call to ** fts5DataRead().
62716. Table for associated with an index on expr, or negative ** of the base register during check-constraint eval
62717. ** The following object holds a copy of the wal-index header content. *** The actual header in the wal-index consists of two copies of this ** object followed by one instance of the WalCkptInfo object. ** For all versions of SQLite through 3.10.0 and probably beyond, ** the locking bytes (WalCkptInfo.aLock) start at offset 120 and ** the total header size is 136 bytes. *** The szPage value can be any power of 2 between 512 and 32768, inclusive. ** Or it can be 1 to represent a 65536-byte page. The latter case was ** added in 3.7.1 when support for 64K pages was added.
62718. ** Returns non-zero if the specified path name should be used verbatim. If ** non-zero is returned from this function, the calling function must simply ** use the provided path name verbatim -OR- resolve it into a full path name ** using the GetFullPathName Win32 API function (if available).
62719. Page size
62720. RTree to search
62721. inner
62722. Least sig. 32 bits of new offset
62723. This function currently works by first transforming the UTF-16 ** encoded string to UTF-8, then invoking sqlite3_prepare(). The ** tricky bit is figuring out the pointer to return in *pzTail.
62724. ** Returns non-zero if the character should be treated as a directory ** separator.
62725. TABLE => nothing
62726. The root page of the b-tree is overfull. In this case call the ** balance_deeper() function to create a new child for the root-page ** and copy the current contents of the root-page to it. The ** next iteration of the do-loop will balance the child page.

62727. ***** Continuing where we left off in mutex_w32.c *****

62728. ** Generate code that will evaluate expression pExpr and store the ** results in register target. The results are guaranteed to appear ** in register target.

62729. Delete all indices associated with this table.

62730. Grow the output buffer so that there is sufficient space to fit the ** largest possible utf-8 character.

62731. ** Return the SQLITE_PREPARE flags for a Vdbe.

62732. ** Return the sqlite3* database handle to which the prepared statement given ** in the argument belongs. This is the same database handle that was ** the first argument to the sqlite3_prepare() that was used to create ** the statement in the first place.

62733. Set to true if constraints may cause a replace

62734. joinop ::= COMMAJOIN

62735. A row is being added to the child table. If a parent row cannot ** be found, adding the child row has violated the FK constraint. *** If this operation is being performed as part of a trigger program ** that is actually a "SET NULL" action belonging to this very ** foreign key, then omit this scan altogether. As all child key ** values are guaranteed to be NULL, it is not possible for adding ** this row to cause an FK violation.

62736. Request is out of range. Return a transient error.

62737. MUST BE LAST (see below)

62738. If the first attempt failed, it might have been due to a race ** with a writer. So get a WRITE lock and try again.

62739. **comment:** ** If we compile with the SQLITE_TEST macro set, then the following block ** of code will give us the ability to simulate a disk I/O error. This ** is used for testing the I/O recovery logic.

A single field is populated if: *** * (pExpr==0). In this case the value is assumed to be an SQL NULL, *** * The expression is a bound variable, and this is a reprepare, or *** * The sqlite3ValueFromExpr() function is able to extract a value ** from the expression (i.e. the expression is a literal value). *** Or, if pExpr is a TK_VECTOR, one field is populated for each of the ** vector components that match either of the two latter criteria listed ** above. *** Before any value is appended to the record, the affinity of the ** corresponding column within index pIdx is applied to it. Before ** this function returns, output parameter *pnExtract is set to the ** number of values appended to the record. *** When this function is called, *ppRec must either point to an object ** allocated by an earlier call to this function, or must be NULL. If it ** is NULL and a value can be successfully extracted, a new UnpackedRecord ** is allocated (and *ppRec set to point to it) before returning. *** Unless an error is encountered, SQLITE_OK is returned. It is not an ** error if a value cannot be extracted from pExpr. If an error does ** occur, an SQLite error code is returned.
62903. We are trying for an exclusive lock but another thread in this ** same process is still holding a shared lock.
62904. If pSortCsr is non-NULL, then this call is being made as part of ** processing for a "... MATCH <expr> ORDER BY rank" query (ePlan is ** set to FT5_PLAN_SORTED_MATCH). pSortCsr is the cursor that will ** return results to the user for this query. The current cursor ** (pCursor) is used to execute the query issued by function ** fts5CursorFirstSorted() above.
62905. ***** Begin file pcache.h *****
62906. Verify that the every entry in the mapping region is reachable ** via the hash table. This turns out to be a really, really expensive ** thing to check, so only do this occasionally - not on every ** iteration.
62907. It is not safe to allow the reader to continue here if frames ** may have been appended to the log before READ_LOCK(0) was obtained. ** When holding READ_LOCK(0), the reader ignores the entire log file, ** which implies that the database file contains a trustworthy ** snapshot. Since holding READ_LOCK(0) prevents a checkpoint from ** happening, this is usually correct. *** However, if frames have been appended to the log (or if the log ** is wrapped and written for that matter) before the READ_LOCK(0) ** is obtained, that is not necessarily true. A checkpointer may ** have started to backfill the appended frames but crashed before ** it finished. Leaving a corrupt image in the database file.
62908. If azData[0] is not an SQL NULL value, it is the rowid of a ** record to delete from the r-tree table. The following block does ** just that.
62909. Destination database handle
62910. ** Enable or disable extension loading. Extension loading is disabled by ** default so as not to open security holes in older applications.
62911. Opcode: NotFound P1 P2 P3 P4 * ** Synopsis: key=r[P3@P4] *** If P4==0 then register P3 holds a blob constructed by MakeRecord. If ** P4>0 then register P3 is the first of P4 registers that form an unpacked ** record. *** Cursor P1 is on an index btree. If the record identified by P3 and P4 ** is not the prefix of any entry in P1 then a jump is made to P2. If P1 ** does contain an entry whose prefix matches the P3/P4 record then control ** falls through to the next instruction and P1 is left pointing at the ** matching entry. *** This operation leaves the cursor in a state where it cannot be ** advanced in either direction. In other words, the Next and Prev ** opcodes do not work after this operation. *** See also: Found, NotExists, NoConflict
62912. ** Propagate all EP_Propagate flags from the Expr.x.pList into ** Expr.flags.
62913. Index of column in parent tbl
62914. Do the comparison
62915. State must be valid.

63287. Context pointer for xChunk callback
63288. **comment:** ** Set bit pngo of the BtShared.pHasContent bitvec. This is called ** when a page that previously contained data becomes a free-list leaf ** page. *** ** The BtShared.pHasContent bitvec exists to work around an obscure ** bug caused by the interaction of two useful IO optimizations surrounding ** free-list leaf pages: *** ** 1) When all data is deleted from a page and the page becomes ** a free-list leaf page, the page is not written to the database ** (as free-list leaf pages contain no meaningful data). Sometimes ** such a page is not even journaled (as it will not be modified, ** why bother journailling it?). *** ** 2) When a free-list leaf page is reused, its content is not read ** from the database or written to the journal file (why should it ** be, if it is not at all meaningful?). *** By themselves, these optimizations work fine and provide a handy ** performance boost to bulk delete or insert operations. However, if ** a page is moved to the free-list and then reused within the same ** transaction, a problem comes up. If the page is not journaled when ** it is moved to the free-list and it is also not journaled when it ** is extracted from the free-list and reused, then the original data ** may be lost. In the event of a rollback, it may not be possible ** to restore the database to its original configuration. *** ** The solution is the BtShared.pHasContent bitvec. Whenever a page is ** moved to become a free-list leaf page, the corresponding bit is ** set in the bitvec. Whenever a leaf page is extracted from the free-list, ** optimization 2 above is omitted if the corresponding bit is already ** set in BtShared.pHasContent. The contents of the bitvec are cleared ** at the end of every transaction.

63489. True (1) if Y,M,D are valid

63490. ** The results of a SELECT can be distributed in several ways, as defined ** by one of the following macros. The "SRT" prefix means "SELECT Result ** Type".

*** SRT_Union Store results as a key in a temporary index ** identified by pDest->iSDParm. *** SRT_Except Remove results from the temporary index pDest->iSDParm. *** SRT_Exists Store a 1 in memory cell pDest->iSDParm if the result ** set is not empty. *** SRT_Discard Throw the results away. This is used by SELECT ** statements within triggers whose only purpose is ** the side-effects of functions. *** All of the above are free to ignore their ORDER BY clause. Those that ** follow must honor the ORDER BY clause. *** SRT_Output Generate a row of output (using the OP_ResultRow ** opcode) for each row in the result set. *** SRT_Mem Only valid if the result is a single column. ** Store the first column of the first result row ** in register pDest->iSDParm then abandon the rest ** of the query. This destination implies "LIMIT 1". *** SRT_Set The result must be a single column. Store each ** row of result as the key in table pDest->iSDParm. ** Apply the affinity pDest->affSdst before storing ** results. Used to implement "IN (SELECT ...)". *** SRT_EphemTab Create an temporary table pDest->iSDParm and store ** the result there. The cursor is left open after ** returning. This is like SRT_Table except that ** this destination uses OP_OpenEphemeral to create ** the table first. *** SRT_Coroutine Generate a co-routine that returns a new row of ** results each time it is invoked. The entry point ** of the co-routine is stored in register pDest->iSDParm ** and the result row is stored in pDest->nDest registers ** starting with pDest->iSdst. *** SRT_Table Store results in temporary table pDest->iSDParm. ** SRT_Fifo This is like SRT_EphemTab except that the table ** is assumed to already be open. SRT_Fifo has ** the additional property of being able to ignore ** the ORDER BY clause. *** SRT_DistFifo Store results in a temporary table pDest->iSDParm. ** But also use temporary table pDest->iSDParm+1 as ** a record of all prior results and ignore any duplicate ** rows. Name means: "Distinct Fifo". *** SRT_Queue Store results in priority queue pDest->iSDParm (really ** an index). Append a sequence number so that all entries ** are distinct. *** SRT_DistQueue Store results in priority queue pDest->iSDParm only if ** the same record has never been stored before. The ** index at pDest->iSDParm+1 hold all prior stores.

63491. Name of trigger

63658. Or if it is a non-periodic sample. Add it in this case too.

63659. Locks are within range

63660. 580

63661. ** Decode a segment-data rowid from the %_data table. This function is ** the opposite of macro FTS5_SEGMENT_ROWID().

63662. Page flags

63663. The table to insert into. aka TABLE

63664. ** Test for access permissions. Return true if the requested permission ** is available, or false otherwise.

63665. Invoke this callback routine

63666. Ran out of input before finding the table name. Return NULL.

63667. ** Truncate the file. *** If the journal file is already on disk, truncate it there. Or, if it ** is still in main memory but is being truncated to zero bytes in size, ** ignore

63668. Call the xFindFunction method on the virtual table implementation ** to see if the implementation wants to overload this function

63669. Sometimes the code for a subquery will be generated more than ** once, if the subquery is part of the WHERE clause in a LEFT JOIN, ** for example. In that case, do not regenerate the code to manifest ** a view or the co-routine to implement a view. The first instance ** is sufficient, though the subroutine to manifest the view does need ** to be invoked again.

63670. The database we are looking in

63671. Read the schema cookie from the database. If it does not match the ** value stored as part of the in-memory schema representation, ** set Parse.rc to SQLITE_SCHEMA.

63672. True if we use the index only

63673. **comment:** There must be at least one argument passed to this function (otherwise ** the non-overloaded version would have been called instead of this one).
label: code-design

63674. YYFALLBACK

63675. #define SQLITE_IGNORE 2 // Also used by sqlite3_authorizer() callback

63676. Number of entries in apMem[]

63677. ** Each sample stored in the sqlite_stat3 table is represented in memory ** using a structure of this type. See documentation at the top of the ** analyze.c source file for additional information.

63678. ** Include standard header files as necessary

63679. At this point variables should be set as follows: ** nPayload Total payload size in bytes ** pPayload Begin writing payload here ** spaceLeft Space available at pPayload. If nPayload>spaceLeft, ** that means content must spill into overflow pages. ** *pnSize Size of the local cell (not counting overflow pages) ** pPrior Where to write the pgno of the first overflow page ** ** Use a call to btreeParseCellPtr() to verify that the values above ** were computed correctly.

63680. Thread-sanitizer reports that the following is an unsafe read, ** as some other thread may be in the process of updating the value ** of the aReadMark[] slot. The assumption here is that if that is ** happening, the other client may only be increasing the value, ** not decreasing it. So assuming either that either the "old" or ** "new" version of the value is read, and not some arbitrary value ** that would never be written by a real client, things are still ** safe.

63681. Do an integrity check on each database file

63682. If the DELETE has generated immediate foreign key constraint ** violations, halt the VDBE and return an error at this point, before ** any modifications to the schema are made. This is because statement ** transactions are not able to rollback schema changes. *** If the SQLITE_DeferFKs flag is set, then this is not required, as ** the statement transaction will not be rolled back even if FK ** constraints are violated.

63683. ** Change the value of the opcode, or P1, P2, P3, or P5 operands ** for a specific instruction.

63684. Transformation type code

63685. **comment:** Magic number 1 is the WAL_CKPT_LOCK lock. Preventing SQLite from ** taking this lock also prevents any checkpoints from occurring. ** todo: really, it's not clear why this might occur, as ** wal_autocheckpoint ought to be turned off.
label: code-design

63686. Close the transaction, if one was opened.

63687. ** Return code from the parse-tree walking primitives and their ** callbacks.

63688. ** Discard the entire contents of the in-memory page-cache.

63689. There is no INDEXED BY clause. Create a fake Index object in local ** variable sPk to represent the rowid primary key index. Make this ** fake index the first in a chain of Index objects with all of the real ** indices to follow

63690. 2147418112

63691. Allocate space for the new sqlite3_shm object. Also speculatively ** allocate space for a new winShmNode and filename.

63692. Total bytes of space to allocate

63693. **comment:** Variable DUMMY1 is initialized to a negative value above. Elsewhere ** in the FTS code the variable that the third argument to xNext points to ** is initialized to zero before the first (*but not necessarily ** subsequent*) call to xNext(). This is done for a particular application ** that needs to know whether or not the tokenizer is being used for ** snippet generation or for some other purpose. *** Extreme care is required when writing code to depend on this ** initialization. It is not a documented part of the tokenizer interface. ** If a tokenizer is used directly by any code outside of FTS, this ** convention might not be respected.
label: code-design

63694. The attempt to extend the existing mapping failed. Free it.

63695. Number of deferred fk violations

63696. The operator

63697. IN/OUT: Left input list

63698. Timezone was set explicitly
63699. Number of backtraces on this alloc
63700. Figure out how many savepoints will still be active after this ** operation. Store this value in nNew. Then free resources associated ** with any savepoints that are destroyed by this operation.
63701. ***** Begin file vacuum.c *****
63702. ** This function does a "phrase" merge of two doclists. In a phrase merge, ** the output contains a copy of each position from the right-hand input ** doclist for which there is a position in the left-hand input doclist ** exactly nDist tokens before it. *** If the docids in the input doclists are sorted in ascending order, ** parameter bDescDoclist should be false. If they are sorted in ascending ** order, it should be passed a non-zero value. *** The right-hand input doclist is overwritten by this function.
63703. ** CAPI3REF: Configure an auto-checkpoint ** METHOD: sqlite3 *** ^The [sqlite3_wal_autocheckpoint(D,N)] is a wrapper around ** [sqlite3_wal_hook()] that causes any database on [database connection] D ** to automatically [checkpoint] ** after committing a transaction if there are N or ** more frames in the [write-ahead log] file. ^Passing zero or ** a negative value as the nFrame parameter disables automatic ** checkpoints entirely. *** ^The callback registered by this function replaces any existing callback ** registered using [sqlite3_wal_hook()]. ^Likewise, registering a callback ** using [sqlite3_wal_hook()] disables the automatic checkpoint mechanism ** configured by this function. *** ^The [wal_autocheckpoint pragma] can be used to invoke this interface ** from SQL. ** ** ^Checkpoints initiated by this mechanism are ** [sqlite3_wal_checkpoint_v2|PASSIVE]. *** ^Every new [database connection] defaults to having the auto-checkpoint ** enabled with a threshold of 1000 or [SQLITE_DEFAULT_WAL_AUTOCHECKPOINT] ** pages. The use of this interface ** is only necessary if the default setting is found to be suboptimal ** for a particular application.
63704. Set this flag to 1
63705. Original value of pNew->u.btree.nEq
63706. Database is closed
63707. outer

63711. ** Set the title string for subsequent allocations.
63712. ** Names of locks. This routine is used to provide debugging output and is not ** a part of an ordinary build.
63713. Index added to make the name unique
63714. OUT: *ppToken is the token text
63715. Context object for function invocation
63716. Copy of idxNum search parameter
63717. Second and subsequent calls get processed here
63718. For looping through SELECT statements
63719. Variable 'dist' stores the number of tokens read since the most ** recent TK_DOT or TK_ON. This means that when a WHEN, FOR or BEGIN ** token is read and 'dist' equals 2, the condition stated above ** to be met. *** Note that ON cannot be a database, table or column name, so ** there is no need to worry about syntax like ** "CREATE TRIGGER ... ON ON.ON BEGIN ..." etc.
63720. ** This function is called when the root page of a b-tree structure is ** overfull (has one or more overflow pages). *** A new child page is allocated and the contents of the current root ** page, including overflow cells, are copied into the child. The root ** page is then overwritten to make it an empty page with the right-child ** pointer pointing to the new page. *** Before returning, all pointer-map entries corresponding to pages ** that the new child-page now contains pointers to are updated. The ** entry corresponding to the new right-child pointer of the root ** page is also updated. *** If successful, *ppChild is set to contain a reference to the child ** page and SQLITE_OK is returned. In this case the caller is required ** to call releasePage() on *ppChild exactly once. If an error occurs, ** an error code is returned and *ppChild is set to 0.
63721. Check for authorization to create an index.
63722. Type field
63723. Total number of rows in FTS table
63724. Used when p4type is P4_EXPR
63725. Uses OS features not supported on host
63726. The root page of the PRIMARY KEY is the table root page
63727. Store result in reg[P2] rather than jump
63728. skip leading spaces
63729. ** Walk the expression tree pExpr and increase the aggregate function ** depth (the Expr.op2 field) by N on every TK_AGG_FUNCTION node. ** This needs to occur when copying a TK_AGG_FUNCTION node from an ** outer query into an inner subquery. *** incrAggFunctionDepth(pExpr,n) is the main routine. incrAggDepth(..) ** is a helper function - a callback for the tree walker.
63730. EVIDENCE-OF: R-59615-42828 A value of 10 (0x0a) means the page is a ** leaf index b-tree page.
63731. **comment:** ** Flags passed as the third argument to sqlite3BtreeCursor(). *** For read-only cursors the wrFlag argument is always zero. For read-write ** cursors it may be set to either (BTREE_WRCSR|BTREE_FORDELETE) or just ** (BTREE_WRCSR). If the BTREE_FORDELETE bit is set, then the cursor will ** only be used by SQLite for the following: *** to seek to and then delete specific entries, and/or *** to read values that will be used to create keys that other ** BTREE_FORDELETE cursors will seek to and delete. *** The BTREE_FORDELETE flag is an optimization hint. It is not used by ** by this, the native b-tree engine of SQLite, but it is available to ** alternative storage engines that might be substituted in place of this ** b-tree system. For alternative storage engines in which a delete of ** the main table row automatically deletes corresponding index rows, ** the FORDELETE flag hint allows those alternative storage engines to ** skip a lot of work. Namely: FORDELETE cursors may treat all SEEK ** and DELETE operations as no-ops, and any READ operation against a ** FORDELETE cursor may return a null row: 0x01 0x00.
label: code-design
63732. If a transient index is required, create it by calling ** sqlite3BtreeCreateTable() with the BTREE_BLOBKEY flag before ** opening it. If a transient table is required, just use the ** automatically created table with root-page 1 (an BLOB_INTKEY table).
63733. Buffer size
63734. ** Add all WhereLoop objects for all tables
63735. ***** NOTES ON THE DESIGN OF THE PAGER ***** This comment block describes invariants that hold when using a rollback ** journal. These invariants do not apply for journal_mode=WAL, ** journal_mode=MEMORY, or journal_mode=OFF. *** Within this comment block, a page is deemed to have been synced ** automatically as soon as it is written when PRAGMA synchronous=OFF. ** Otherwise, the page is not synced until the xSync method of the VFS ** is called successfully on the file containing the page. *** Definition: A page of the database file is said to be "overwriteable" if ** one or more of the following are true about the page: *** (a) The original content of the page as it was at the beginning of ** the transaction has been written into the rollback journal and ** synced. *** (b) The page was a freelist leaf page at the start of the transaction. *** (c) The page number is greater than the largest page that existed in ** the database file at the start of the transaction. *** (1) A page of the database file is never overwritten unless one of the ** following are true: *** (a) The page and all other pages on the same sector are overwriteable. *** (b) The atomic page write optimization is enabled, and the entire ** transaction other than the update of the transaction sequence ** number consists of a single page change. *** (2) The content of a page written into the rollback journal exactly matches ** both the content in the database when the rollback journal was written ** and the content in the database at the beginning of the current ** transaction. *** (3) Writes to the database file are an integer multiple of the page size ** in length and are aligned on a page boundary. *** (4) Reads from the database file are either aligned on a page boundary and ** an integer multiple of the page size in length or are taken from the ** first 100 bytes of the database file. *** (5) All writes to the database file are synced prior to the rollback journal ** being deleted, truncated, or zeroed. *** (6) If a master journal file is used, then all writes to the database file ** are synced prior to the master journal being deleted. *** Definition: Two databases (or the same database at two points in time) ** are said to be "logically equivalent" if they give the same answer to ** all queries. Note in particular the content of freelist leaf ** pages can be changed arbitrarily without affecting the logical equivalence ** of the database. *** (7) At any time, if any subset, including the empty set and the total set, ** of the unsynced changes to a rollback journal are removed and the ** journal is rolled back, the resulting database file will be logically ** equivalent to the database file at the beginning of the transaction. *** (8) When a transaction is rolled back, the xTruncate method of the VFS ** is called to restore the database file to the same size it was at ** the beginning of the transaction. (In some VFSes, the xTruncate ** method is a no-op, but that does not change the fact the SQLite will ** invoke it.) *** (9) Whenever the database file is modified, at least one bit in the range ** of bytes from 24 through 39 inclusive will be changed prior to releasing ** the EXCLUSIVE lock, thus signaling other connections on the same ** database to flush their caches. *** (10) The pattern of bits in bytes 24 through 39 shall not repeat in less ** than one billion transactions. *** (11) A database file is well-formed at the beginning and at

the conclusion ** of every transaction. *** (12) An EXCLUSIVE lock is held on the database file when writing to ** the database file. *** (13) A SHARED lock is held on the database file while reading any ** content out of the database file. ***

63736. ** Register a new collation sequence with the database handle db.

63737. Current node image

63738. Decode the position list tail at the start of the page

63739. Open the sqlite_stat1 table on this cursor

63740. ** Return status data for a single loop within query pStmt.

63741. Figure out how many records are in the journal. Abort early if ** the journal is empty.

63742. Affinity to use

63743. ** The second argument to this function contains the text of an SQL statement ** that returns a single integer value. The statement is compiled and executed ** using database connection db. If successful, the integer value returned ** is written to *piVal and SQLITE_OK returned. Otherwise, an SQLite error ** code is returned and the value of *piVal after returning is not defined.

63744. First argument passed to xConflict

63745. If the secure_delete option is enabled, then ** always fully overwrite deleted information with zeros.

63746. ** When a sub-program is executed (OP_Program), a structure of this type ** is allocated to store the current value of the program counter, as ** well as the current memory cell array and various other frame specific ** values stored in the Vdbe struct. When the sub-program is finished, ** these values are copied back to the Vdbe from the VdbeFrame structure, ** restoring the state of the VM to as it was before the sub-program ** began executing. *** The memory for a VdbeFrame object is allocated and managed by a memory ** cell in the parent (calling) frame. When the memory cell is deleted or ** overwritten, the VdbeFrame object is not freed immediately. Instead, it ** is linked into the Vdbe.pDelFrame list. The contents of the Vdbe.pDelFrame ** list is deleted when the VM is reset in VdbeHalt(). The reason for doing ** this instead of deleting the VdbeFrame immediately is to avoid recursive ** calls to sqlite3VdbeMemRelease() when the memory cells belonging to the ** child frame are released. *** The currently executing frame is stored in Vdbe.pFrame. Vdbe.pFrame is ** set to NULL if the currently executing frame is the main program.

63747. WHEN clause for the trigger

63748. No WHERE clause

63749. Can't reestablish the shared lock. Sqlite can't deal, this is ** a critical I/O error

63750. True if PAGER_GET_NOCONTENT is set

63751. ** Deprecated external interface. Internal/core SQLite code ** should call sqlite3TransferBindings. *** It is misuse to call this routine with statements from different ** database connections. But as this is a deprecated interface, we ** will not bother to check for that condition. *** If the two statements contain a different number of bindings, then ** an SQLITE_ERROR is returned. Nothing else can go wrong, so otherwise ** SQLITE_OK is returned.

63752. 255

63753. Bytes of data available in buffer

63754. Put error message here if not 0

63755. The following are used by the fts3_snippet.c module.

63756. For each expression in the list

63757. **comment:** ** The macro MEMDB is true if we are dealing with an in-memory database. ** We do this as a macro so that if the SQLITE OMIT_MEMORYDB macro is set, ** the value of MEMDB will be a constant and the compiler will optimize ** out code that would never execute.

label: code-design

63758. ** Recommended number of samples for sqlite_stat4

63759. Memory registers holding LIMIT & OFFSET counters

63760. (pKey1/nKey1) is a number or a null

63761. No need to log a failure to lock

63762. Min-heap used for analyzing cell coverage

63763. Index for p->aIndex[]

63764. Load table details if required

63765. ** Given table pTab, return a list of all the triggers attached to ** the table. The list is connected by Trigger.pNext pointers. *** All of the triggers on pTab that are in the same database as pTab ** are already attached to pTab->pTrigger. But there might be additional ** triggers on pTab in the TEMP schema. This routine prepends all ** TEMP triggers on pTab to the beginning of the pTab->pTrigger list ** and returns the combined list. *** To state it another way: This routine returns a list of all triggers ** that fire off of pTab. The list will include any TEMP triggers on ** pTab as well as the triggers listed in pTab->pTrigger.

63766. source and destination must both be WITHOUT ROWID or not

63767. **comment:** Loop through all %_segdir entries for segments in this index with ** levels equal to or greater than iAbsLevel. As each entry is visited, ** updated it to set (level = -1) and (idx = N), where N is 0 for the ** oldest segment in the range, 1 for the next oldest, and so on. *** In other words, move all segments being promoted to level -1, ** setting the "idx" fields as appropriate to keep them in the same ** order. The contents of level -1 (which is never used, except ** transiently here), will be moved back to level iAbsLevel below.

label: code-design

63768. ** Return true if the iterator is at EOF or if an error has occurred. ** False otherwise.

63769. Previously obtained value for P4

63770. **comment:** Loop through the tables in the main database. For each, do ** an "INSERT INTO vacuum_db.xxx SELECT * FROM main.xxx;" to copy ** the contents to the temporary database.

label: code-design

63772. CURTYPE_SORTER. Sorter object

63773. Elements in aOp[]

63774. pPager->state = PAGER_UNLOCK;

63775. **comment:** Each page cache (or PCache) belongs to a PGroup. A PGroup is a set ** of one or more PCaches that are able to recycle each other's unpinned ** pages when they are under memory pressure. A PGroup is an instance of ** the following object. *** This page cache implementation works in one of two modes: ** ** (1) Every PCache is the sole member of its own PGroup. There is ** one PGroup per PCache. *** (2) There is a single global PGroup that all PCaches are a member ** of. *** Mode 1 uses more memory (since PCache instances are not able to rob ** unused pages from other PCaches) but it also operates without a mutex, ** and is therefore often faster. Mode 2 requires a mutex in order to be ** threadsafe, but recycles pages more efficiently. *** For mode (1), PGroup.mutex is NULL. For mode (2) there is only a single ** PGroup which is the pcache1.grp global variable and its mutex is ** SQLITE_MUTEX_STATIC_LRU.

label: code-design

63776. Column names corresponding to IDLIST.

63777. ** CAPI3REF: Set a table filter on a Session Object. *** The second argument (xFilter) is the "filter callback". For changes to rows ** in tables that are not attached to the Session object, the filter is called ** to determine whether changes to the table's rows should be tracked or not. ** If xFilter returns 0, changes is not tracked. Note that once a table is ** attached, xFilter will not be called again.

63778. ** Scan the column type name zType (length nType) and return the ** associated affinity type. *** This routine does a case-independent search of zType for the ** substrings in the following table. If one of the substrings is ** found, the corresponding affinity is returned. If zType contains ** more than one of the substrings, entries toward the top of ** the table take priority. For example, if zType is 'BLOBINT', ** SQLITE_AFF_INTEGER is returned. *** Substring | Affinity ** ----- ** INT | SQLITE_AFF_INTEGER ** CHAR | SQLITE_AFF_TEXT ** CLOB | SQLITE_AFF_TEXT ** TEXT | SQLITE_AFF_TEXT ** BLOB' | SQLITE_AFF_BLOB ** REAL' | SQLITE_AFF_REAL ** FLOA' | SQLITE_AFF_REAL ** DOUB' | SQLITE_AFF_REAL *** If none of the substrings in the above table are found, ** SQLITE_AFF_NUMERIC is returned.

63779. Number of fields in pRec

63780. ** Given the list of WhereLoop objects at pWInfo->pLoops, this routine ** attempts to find the lowest cost path that visits each WhereLoop ** once. This path is then loaded into the pWInfo->a[].pWLoop fields. *** Assume that the total number of output rows that will need to be sorted ** will be nRowEst (in the 10*log2 representation). Or, ignore sorting ** costs if nRowEst==0. *** Return SQLITE_OK on success or SQLITE_NOMEM of a memory allocation ** error occurs.

63781. Parse array

63782. ** This is a helper function used by sessionMergeUpdate(). *** When this function is called, both *paOne and *paTwo point to a value ** within a change record. Before it returns, both have been advanced so ** as to point to the next value in the record. *** If, when this function is called, *paTwo points to a valid value (i.e. ** *paTwo[0] is not 0x00 - the "no value" placeholder), a copy of the *paTwo ** pointer is returned and *pnVal is set to the number of bytes in the ** serialized value. Otherwise, a copy of *paOne is returned and *pnVal ** set to the number of bytes in the value at *paOne. If *paOne points ** to the "no value" placeholder, *pnVal is set to 1. In other words: *** if(*paTwo is valid) return *paTwo; ** return *paOne; **

63783. Value for "end_block" field

63784. a column type code

63785. Store result as data with an automatic rowid

63786. Initialize the structure. The sqlite3_index_info structure contains ** many fields that are declared "const" to prevent xBestIndex from ** changing them. We have to do some funky casting in order to ** initialize those fields.

63787. ** The following set of routines are used to disable the simulated ** I/O error mechanism. These routines are used to avoid simulated ** errors in places where we do not care about errors. *** Unless -DSQLITE_TEST=1 is used, these routines are all no-ops ** and generate no code.

63788. Drop all SQLITE_MASTER table and index entries that refer to the ** table. The program name loops through the master table and deletes ** every row that refers to a table of the same name as the one being ** dropped. Triggers are handled separately because a trigger can be ** created in the temp database that refers to a table in another ** database.

63789. ** Locate a user function given a name, a number of arguments and a flag ** indicating whether the function prefers UTF-16 over UTF-8. Return a ** pointer to the FuncDef structure that defines that function, or return ** NULL if the function does not exist. *** If the createFlag argument is true, then a new (blank) FuncDef ** structure is created and linked into the "db" structure if a ** no matching function previously existed. *** If nArg is -2, then the first valid function found is returned. A ** function is valid if xSFunc is non-zero. The nArg==(-2) ** case is used to see if zName is a valid function name for some number ** of arguments. If nArg is -2, then createFlag must be 0. *** If createFlag is false, then a function with the required name and ** number of arguments may be returned even if the eTextRep flag does not ** match that requested.

63790. True if aOverflow is valid

63791. Table on the left with matching column name

63792. Text encoding used by this database

63793. Make the new connection a child of the unixShmNode

63794. If the VM did not run to completion or if it encountered an ** error, then it might not have been halted properly. So halt ** it now.

63795. EVIDENCE-OF: R-02776-14802 The cell pointer array consists of K 2-byte ** integer offsets to the cell contents.

63796. True exponent is either not used or is well-formed

63797. OUT: SQLITE_INSERT, DELETE or UPDATE

63798. Added ???

63799. ** 2006 June 7 *** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This header file defines the SQLite interface for use by ** shared libraries that want to be imported as extensions into ** an SQLite instance. Shared libraries that intend to be loaded ** as extensions by SQLite should #include this file instead of ** sqlite3.h.

63800. Number of references to columns in other FROM clauses

63801. ** Allowed values for Select.selFlags. The "SF" prefix stands for ** "Select Flag". *** Value constraints (all checked via assert()) ** SF_HasAgg == NC_HasAgg ** SF_MinMaxAgg == NC_MinMaxAgg == SQLITE_FUNC_MINMAX ** SF_FixedLimit == WHERE_USE_LIMIT

63802. If there is a doclist-index, check that it looks right.

63803. **comment:** "[...]" immediately follows the "*". We have to do a slow ** recursive search in this case, but it is an unusual case.
label: code-design

63804. ** Return the column of index pIdx that corresponds to table ** column iCol. Return -1 if not found.

63805. ** Memory map or remap the file opened by file-descriptor pFd (if the file ** is already mapped, the existing mapping is replaced by the new). Or, if ** there already exists a mapping for this file, and there are still ** outstanding xFetch() references to it, this function is a no-op. *** If parameter nByte is non-negative, then it is the requested size of ** the mapping to create. Otherwise, if nByte is less than zero, then the ** requested size is the size of the file on disk. The actual size of the ** created mapping is either the requested size or the value configured ** using SQLITE_FCNTL_MMAP_LIMIT, whichever is smaller. *** ** SQLITE_OK is returned if no error occurs (even if the mapping is not ** recreated as a result of outstanding references) or an SQLite error ** code otherwise.

63806. ** Populate the Fts5Config.zContentExprlist string.

63807. Additional methods may be added in future releases

63808. The comparison operator

63809. Connection that caused SQLITE_LOCKED

63810. Read the wal-index header.

63811. ** Return true if the parser passed as the first argument is being ** used to code a trigger that is really a "SET NULL" action belonging ** to trigger pFKey.

63812. Number of errors reported

63813. Subroutine for resetting the accumulator

63814. ** Set the value if the iSrcLine field for the previously coded instruction.

63815. ** Free any overflow pages associated with the given Cell. Write the ** local Cell size (the number of bytes on the original page, omitting ** overflow) into *pnSize.

63816. ** This function searches pList for an entry that matches the iCol-th column ** of index pIdx. *** If such an expression is found, its index in pList->a[] is returned. If ** no expression is found, -1 is returned.

63817. Usable size of mapped region

63818. compress=? parameter (or NULL)

63819. Initialization context

63820. The WHERE clause. May be NULL

63821. The flags specified at open()

63822. FTS5_AND node to advance

63823. Value returned by conflict handler

63824. Populate the coverage-checking heap for leaf pages

63825. SQLITE_OS_WIN_THREADS

63826. ***** Begin file where.c *****

63827. Insert an element into the hash table pH. The key is pKey ** and the data is "data". *** If no element exists with a matching key, then a new ** element is created and NULL is returned. *** If another element already exists with the same key, then the ** new data replaces the old data and the old data is returned. ** The key is not copied in this instance. If a malloc fails, then ** the new data is returned and the hash table is unchanged. *** If the "data" parameter to this function is NULL, then the ** element corresponding to "key" is removed from the hash table.

63828. Verifies FORDELETE and AUXDELETE flags

63829. First try to append the term to the current node. Return early if ** this is possible.

63830. ** Return a section of the pPage->aData to the freelist. ** The first byte of the new free block is pPage->aData[iStart] ** and the size of the block is iSize bytes. *** Adjacent freeblocks are coalesced. *** Note that even though the freeblock list was checked by btreeInitPage(), ** that routine will not detect overlap between cells or freeblocks. Nor ** does it detect cells or freeblocks that encroach into the reserved bytes ** at the end of the page. So do additional corruption checks inside this ** routine and return SQLITE_CORRUPT if any problems are found.

63831. Flags to sqlite3BtreeOpen()

63832. tcons ::= CONSTRAINT nm

63833. If we compiled with the SQLITE_NO_SYNC flag, then syncing is a ** no-op

63834. Find an existing tokenizer

63835. defined(SQLITE_WIN32_HAS_ANSI)

63836. EVIDENCE-OF: R-61275-35157 The SQLITE_CONFIG_MEMSTATUS option takes ** single argument of type int, interpreted as a boolean, which enables ** or disables the collection of memory allocation statistics.

63837. ** Read data from a blob handle.

63838. xSleep
63839. ** Return the maximum height of any expression tree referenced ** by the select statement passed as an argument.
63840. Info about locks on this inode
63841. The WhereClause to be initialized
63842. mem1.flags = 0; // Will be initialized by sqlite3VdbeSerialGet()
63843. Return code for this function
63844. Allocate and populate the context object.
63845. The i-th index expression
63846. **** Begin dot-file Locking
***** The dotfile locking implementation uses the existence of separate lock ** files (really a directory) to control access to the database. This works ** on just about every filesystem imaginable. But there are serious downsides: *** (1) There is zero concurrency. A single reader blocks all other ** connections from reading or writing the database. *** (2) An application crash or power loss can leave stale lock files ** sitting around that need to be cleared manually. *** Nevertheless, a dotlock is an appropriate locking mode for use if no ** other locking strategy is available. *** Dotfile locking works by creating a subdirectory in the same directory as ** the database and with the same name but with a ".lock" extension added. ** The existence of a lock directory implies an EXCLUSIVE lock. All other ** lock types (SHARED, RESERVED, PENDING) are mapped into EXCLUSIVE.
63847. Search the hash table or tables for an entry matching page number ** pgno. Each iteration of the following for() loop searches one ** hash table (each hash table indexes up to HASHTABLE_NPAGE frames). *** This code might run concurrently to the code in walIndexAppend() ** that adds entries to the wal-index (and possibly to this hash ** table). This means the value just read from the hash ** slot (aHash[iKey]) may have been added before or after the ** current read transaction was opened. Values added after the ** read transaction was opened may have been written incorrectly - ** i.e. these slots may contain garbage data. However, we assume ** that any slots written before the current read transaction was ** opened remain unmodified. *** For the reasons above, the if(..) condition featured in the inner ** loop of the following block is more stringent than would be required ** if we had exclusive access to the hash-table: *** (aPgno[iFrame]==pgno): ** This condition filters out normal hash-table collisions. *** (iFrame<=iLast): ** This condition filters out entries that were added to the hash ** table after the current read-transaction had started.
63848. Snippet iterator
63849. ** Return the number of dirty pages currently in the cache, as a percentage ** of the configured cache size.
63850. Enable recursive triggers
63851. Iterator used to gather data from index
63852. Don't do any authorization checks if the database is initialising ** or if the parser is being invoked from within sqlite3_declare_vtab.
63853. The parser's stack
63854. Absolute level number to work on
63855. ***** End of vacuum.c *****
63856. Content of this chunk
63857. Address of OP_Explain (or 0)
63858. ***** The following routines are the only publically visible identifiers in this ** file. Call the following routines in order to register the various SQL ** functions and the virtual table implemented by this file.*****
63859. Last field of the record
63860. Est. number of distinct keys less than this sample
63861. ** The following is guaranteed when this function is called: *** a) the WRITER lock is held, ** b) the entire log file has been checkpointed, and ** c) any existing readers are reading exclusively from the database ** file - there are no readers that may attempt to read a frame from ** the log file. *** This function updates the shared-memory structures so that the next ** client to write to the database (which may be this one) does so by ** writing frames into the start of the log file. *** The value of parameter salt1 is used as the aSalt[1] value in the ** new wal-index header. It should be passed a pseudo-random value (i.e. ** one obtained from sqlite3_randomness()).
63862. The WHERE clause to be searched
63863. Alternate addrEofA if B is uninitialized
63864. 750
63865. The following assert statements check that the binary search code ** above found the right answer. This block serves no purpose other ** than to invoke the asserts.
63866. failed to open/create the lock directory
63867. Index used to optimize scan, or NULL
63868. ** This function does all the work for both the xConnect and xCreate methods. ** These tables have no persistent representation of their own, so xConnect ** and xCreate are identical operations.
63869. If the child table is the same as the parent table, then add terms ** to the WHERE clause that prevent this entry from being scanned. ** The added WHERE clause terms are like this: *** \$current_rowid!=rowid ** NOT(\$current_a==a AND \$current_b==b AND ...) *** The first form is used for rowid tables. The second form is used ** for WITHOUT ROWID tables. In the second form, the primary key is ** (a,b,...)
63870. CREATE VIEW name AS... without an argument list. Construct ** the column names from the SELECT statement that defines the view.
63871. ** Sync the journal. In other words, make sure all the pages that have ** been written to the journal have actually reached the surface of the ** disk and can be restored in the event of a hot-journal rollback. *** If the Pager.noSync flag is set, then this function is a no-op. ** Otherwise, the actions required depend on the journal-mode and the ** device characteristics of the file-system, as follows: *** * If the journal file is an in-memory journal file, no action need ** be taken. ** * Otherwise, if the device does not support the SAFE_APPEND property, ** then the nRec field of the most recently written journal header ** is updated to contain the number of journal records that have ** been written following it. If the pager is operating in full-sync ** mode, then the journal file is synced before this field is updated. *** * If the device does not support the SEQUENTIAL property, then ** journal file is synced. ** * Or, in pseudo-code: *** if(NOT <in-memory journal>) { ** if(NOT SAFE_APPEND){ ** if(<full-sync mode>) xSync(<journal file>); ** <update nRec field> ** } ** if(NOT SEQUENTIAL) xSync(<journal file>); ** } *** If successful, this routine clears the PGHDR_NEED_SYNC flag of every ** page currently held in memory before returning SQLITE_OK. If an IO ** error is encountered, then the IO error code is returned to the caller.
63872. ** Obtain or release the mutex needed to access global data structures.
63873. ** Open a new database handle.
63874. Number of sub-vdbes seen so far
63875. The antipenultimate character of the master journal name must ** be "9" to avoid name collisions when using 8+3 filenames.
63876. If the blob handle is not open at this point, open it and seek ** to the requested entry.
63877. ** Convert a Microsoft Unicode string to UTF-8. ** Space to hold the returned string is obtained from sqlite3_malloc().
63878. Close the open database handle and VFS object.
63879. Fsync the rollback journal before ** writing this page to the database
63880. Opcode: SCopy P1 P2 * * * Synopsis: r[P2]=r[P1] ** Make a shallow copy of register P1 into register P2. ** This instruction makes a shallow copy of the value. If the value ** is a string or blob, then the copy is only a pointer to the ** original and hence if the original changes so will the copy. ** Worse, if the original is deallocated, the copy becomes invalid. ** Thus the program must guarantee that the original will not change ** during the lifetime of the copy. Use OP_Copy to make a complete ** copy.
63881. Code generator context
63882. If the log file is not already open, but does exist in the file-system, ** it may need to be checkpointed before the connection can switch to ** rollback mode. Open it now so this can happen.
63883. Used to build up table PK declaration
63884. Number of bytes written by seekAndWrite
63885. **comment:** If ORDER BY makes no difference in the output then neither does ** DISTINCT so it can be removed too.
label: code-design
63886. ** Convert OP_Column opcodes to OP_Copy in previously generated code. ** This routine runs over generated VDBE code and translates OP_Column ** opcodes into OP_Copy when the table is being accessed via co-routine ** instead of via table lookup. ** If the bIncrRowid parameter is 0, then any OP_Rowid instructions on ** cursor iTabCur are transformed into OP_Null. Or, if bIncrRowid is non-zero, ** then each OP_Rowid is transformed into an instruction to increment the ** value stored in its output register.

63887. This is an mmap page object
63888. Jump here to continue with next row
63889. ** Add an entry to the in-memory hash table. The key is the concatenation ** of bByte and (pToken/nToken). The value is (iRowid/iCol/iPos). *** (bByte || pToken) -> (iRowid,iCol,iPos) *** Or, if iCol is negative, then the value is a delete marker.

 64184. Label to jump to if WHEN is false
 64185. **comment:** ** Deferred and Immediate FKs ** ----- ** Foreign keys in SQLite come in two flavours: deferred and immediate. ** If an immediate foreign key constraint is violated, ** SQLITE_CONSTRAINT_FOREIGNKEY is returned and the current ** statement transaction rolled back. If a ** deferred foreign key constraint is violated, no action is taken ** immediately. However if the application attempts to commit the ** transaction before fixing the constraint violation, the attempt fails. *** Deferred constraints are implemented using a simple counter associated ** with the database handle. The counter is set to zero each time a ** database transaction is opened. Each time a statement is executed ** that causes a foreign key violation, the counter is incremented. Each ** time a statement is executed that removes an existing violation from ** the database, the counter is decremented. When the transaction is ** committed, the commit fails if the current value of the counter is ** greater than zero. This scheme has two big drawbacks: *** * When a commit fails due to a deferred foreign key constraint, ** there is no way to tell which foreign constraint is not satisfied, ** or which row it is not satisfied for. *** * If the database contains foreign key violations when the ** transaction is opened, this may cause the mechanism to malfunction. *** Despite these problems, this approach is adopted as it seems simpler ** than the alternatives. *** INSERT operations: *** I.1) For each FK for which the table is the child table, search ** the parent table for a match. If none is found increment the ** constraint counter. *** I.2) For each FK for which the table is the parent table, ** search the child table for rows that correspond to the new ** row in the parent table. Decrement the counter for each row ** found (as the constraint is now satisfied). *** DELETE operations: *** D.1) For each FK for which the table is the child table, ** search the parent table for a row that corresponds to the ** deleted row in the child table. If such a row is not found, ** decrement the counter. *** D.2) For each FK for which the table is the parent table, search ** the child table for rows that correspond to the deleted row ** in the parent table. For each found increment the counter. *** UPDATE operations: *** An UPDATE command requires that all 4 steps above are taken, but only ** for FK constraints for which the affected columns are actually ** modified (values must be compared at runtime). *** Note that I.1 and D.1 are very similar operations, as are I.2 and D.2. ** This simplifies the implementation a bit. *** For the purposes of immediate FK constraints, the OR REPLACE conflict ** resolution is considered to delete rows before the new row is inserted. ** If a delete caused by OR REPLACE violates an FK constraint, an exception ** is thrown, even if the FK constraint would be satisfied after the new ** row is inserted. *** Immediate constraints are usually handled similarly. The only difference ** is that the counter used is stored as part of each individual statement ** object (struct Vdbe). If, after the statement has run, its immediate ** constraint counter is greater than zero, ** it returns SQLITE_CONSTRAINT_FOREIGNKEY ** and the statement transaction is rolled back. An exception is an INSERT ** statement that inserts a single row only (no triggers). In this case, ** instead of using a counter, an exception is thrown immediately if the ** INSERT violates a foreign key constraint. This is necessary as such ** an INSERT does not open a statement transaction. *** TODO: How should dropping a table be handled? How should renaming a ** table be handled? *** Query API Notes ** ----- *** Before coding an UPDATE or DELETE row operation, the code-generator ** for those two operations needs to know whether or not the operation ** requires any FK processing and, if so, which columns of the original ** row are required by the FK processing VDBE code (i.e. if FKS were ** implemented using triggers, which of the old.* columns would be ** accessed). No information is required by the code-generator before ** coding an INSERT operation. The functions used by the UPDATE/DELETE ** generation code to query for this information are: *** sqlite3FkRequired() - Test to see if FK processing is required. ** sqlite3FkOldmask() - Query for the set of required old.* columns. *** Externally accessible module functions ** ----- *** sqlite3FkCheck() - Check for foreign key violations. **
 sqlite3FkActions() - Code triggers for ON UPDATE/ON DELETE actions. ** sqlite3FkDelete() - Delete an FKey structure.

 64214. same as TK_NOTNULL, synopsis: if r[P1]!=NULL goto P2
 64215. **comment:** ***** This file is an amalgamation of many separate C source files from SQLite ** version 3.20.0. By combining all the individual C code files into this ** single large file, the entire code can be compiled as a single translation ** unit. This allows many compilers to do optimizations that would not be ** possible if the files were compiled separately. Performance improvements ** of 5% or more are commonly seen when SQLite is compiled as a single ** translation unit. *** This file is all you need to compile SQLite. To use SQLite in other ** programs, you need this file and the "sqlite3.h" header file that defines ** the programming interface to the SQLite library. (If you do not have ** the "sqlite3.h" header file at hand, you will find a copy embedded within ** the text of this file. Search for "Begin file sqlite3.h" to find the start ** of the embedded sqlite3.h header file.) Additional code files may be needed ** if you want a wrapper to interface SQLite with your choice of programming ** language. The code for the "sqlite3" command-line shell is also in a ** separate file. This file contains only code for the core SQLite library.

64242. Collating sequence. If NULL, use the default
64243. If the bit corresponding to this variable in Vdbe.expmask is set, then ** binding a new value to this variable invalidates the current query plan. ** **
IMPLEMENTATION-OF: R-48440-37595 If the specific value bound to host ** parameter in the WHERE clause might influence the choice of query plan ** for a statement, then the statement will be automatically recompiled, ** as if there had been a schema change, on the first sqlite3_step() call ** following any change to the bindings of that parameter.
64244. Number of columns in parent key
64245. Current offset into pData
64246. ** Generate code for scalar subqueries used as a subquery expression, EXISTS, ** or IN operators. Examples: ** ** (SELECT a FROM b) -- subquery **
EXISTS (SELECT a FROM b) -- EXISTS subquery ** x IN (4,5,11) -- IN operator with list on right-hand side ** x IN (SELECT a FROM b) -- IN operator with subquery on the right ** ** The pExpr parameter describes the expression that contains the IN ** operator or subquery. ** ** If parameter isRowid is non-zero, then expression pExpr is guaranteed ** to be of the form "<rowid> IN (?, ?, ?)", where <rowid> is a reference ** to some integer key column of a table B-Tree. In this case, use an ** intkey B-Tree to store the set of IN(...) values instead of the usual ** (slower) variable length keys B-Tree. ** ** If rMayBeNull is non-zero, that means that the operation is an IN ** (not a SELECT or EXISTS) and that the RHS might contain NULLs. ** All this routine does is initialize the register given by rMayBeNull ** to NULL. Calling routines will take care of changing this register ** value to non-NUL if the RHS is NULL-free. ** ** For a SELECT or EXISTS operator, return the register that holds the ** result. For a multi-column SELECT, the result is stored in a contiguous ** array of registers and the return value is the register of the left-most ** result column. Return 0 for IN operators or if an error occurs.
64247. **comment:** ** Do a deep comparison of two expression trees. Return 0 if the two ** expressions are completely identical. Return 1 if they differ only ** by a COLLATE operator at the top level. Return 2 if there are differences ** other than the top-level COLLATE operator. ** ** If any subelement of pB has Expr.iTable==(-1) then it is allowed ** to compare equal to an equivalent element in pA with Expr.iTable==iTab. ** ** The pA side might be using TK_REGISTER. If that is the case and pB is ** not using TK_REGISTER but is otherwise equivalent, then still return 0. ** ** Sometimes this routine will return 2 even if the two expressions ** really are equivalent. If we cannot prove that the expressions are ** identical, we return 2 just to be safe. So if this routine ** returns 2, then you do not really know for certain if the two ** expressions are the same. But if you get a 0 or 1 return, then you ** can be sure the expressions are the same. In the places where ** this routine is used, it does not hurt to get an extra 2 - that ** just might result in some slightly slower code. But returning ** an incorrect 0 or 1 could lead to a malfunction. ** ** If pParse is not NULL then TK_VARIABLE terms in pA with bindings in ** pParse->pReprepare can be matched against literals in pB. The ** pParse->pVdbe->expmask bitmask is updated for each variable referenced. ** If pParse is NULL (the normal case) then any TK_VARIABLE term in ** Argument pParse should normally be NULL. If it is not NULL and pA or ** pB causes a return value of 2.

64398. FTS table handle

64399. The Parse structure

64400. ** Round up a number to the next larger multiple of 8. This is used ** to force 8-byte alignment on 64-bit architectures.

64401. ** Check invariants on a Mem object. ** This routine is intended for use inside of assert() statements, like ** this: assert(sqlite3VdbeCheckMemInvariants(pMem));

64402. Disable mutex on core

64403. Null-terminated column definition

64404. **comment:** ** CAPI3REF: Application Defined Page Cache. ** KEYWORDS: {page cache} ** ** ^{The [sqlite3_config]([SQLITE_CONFIG_PCACHE2], ...)} interface can ** register an alternative page cache implementation by passing in an ** instance of the sqlite3_pcache_methods2 structure.^ ** In many applications, most of the heap memory allocated by ** SQLite is used for the page cache. ** By implementing a ** custom page cache using this API, an application can better control ** the amount of memory consumed by SQLite, the way in which ** that memory is allocated and released, and the policies used to ** determine exactly which parts of a database file are cached and for ** how long. ** The alternative page cache mechanism is an ** extreme measure that is only needed by the most demanding applications. ** The built-in page cache is recommended for most uses. ** ^{The contents of the sqlite3_pcache_methods2 structure are copied to an ** internal buffer by SQLite within the call to [sqlite3_config]. Hence ** the application may discard the parameter after the call to ** [sqlite3_config] returns.^ ** [[the xInit() page cache method]] ** ^{The xInit() method is called once for each effective ** call to [sqlite3_initialize()].^ ** (usually only once during the lifetime of the process).^ ** [[the xShutdown() page cache method]] ** ^{The xShutdown() method is called by [sqlite3_shutdown()]. ** It can be used to clean up ** any outstanding resources before process shutdown, if required. ** ^{The xShutdown() method may be NULL. ** ^{SQLite automatically serializes calls to the xInit method, ** so the xInit method need not be threadsafe. ^{The ** xShutdown method is only called from [sqlite3_shutdown()] so it does ** not need to be threadsafe either. All other methods must be threadsafe ** in multithreaded applications. ** ^{SQLite will never invoke xInit() more than once without an intervening ** call to xShutdown(). ** ^{[[the xCreate() page cache methods]] ** ^{SQLite invokes the xCreate() method to construct a new cache instance. ** SQLite will typically create one cache instance for each open database file, ** though this is not guaranteed. ^{The ** first parameter, szPage, is the size in bytes of the pages that must ** be allocated by the cache. ^{szPage will always a power of two. ^{The ** second parameter szExtra is a number of bytes of extra storage ** associated with each page cache entry. ^{The szExtra parameter will ** a number less than 250. SQLite will use the ** extra szExtra bytes on each page to store metadata about the underlying ** database page on disk. The value passed into szExtra depends ** on the SQLite version, the target platform, and how SQLite was compiled. ** ^{The third argument to xCreate(), bPurgeable, is true if the cache being ** created will be used to cache database pages of a file stored on disk, or ** false if it is used for an in-memory database. The cache implementation ** does not have to do anything special based with the value of bPurgeable; ** it is purely advisory. ^{On a cache where bPurgeable is false, SQLite will ** never invoke xUnpin() except to deliberately delete a page. ** ^{In other words, calls to xUnpin() on a cache with bPurgeable set to ** false will always have the "discard" flag set to true. ** ^{Hence, a cache created with bPurgeable false will ** never contain any unpinned pages. ** ^{[[the xCachesize() page cache method]] ** ^{The xCachesize() method may be called at any time by SQLite to set the ** suggested maximum cache-size (number of pages stored by) the cache ** instance passed as the first argument. This is the value configured using ** the SQLite "[PRAGMA cache_size]" command.)^ As with the bPurgeable ** parameter, the implementation is not required to do anything with this ** value; it is advisory only. ** ^{[[the xPagecount() page cache methods]] ** ^{The xPagecount() method must return the number of pages currently ** stored in the cache, both pinned and unpinned. ** ^{[[the xFetch() page cache methods]] ** ^{The xFetch() method locates a page in the cache and returns a pointer to ** an sqlite3_pcache_page object associated with that page, or a NULL pointer. ** ^{The pBuf element of the returned sqlite3_pcache_page object will be a ** pointer to a buffer of szPage bytes used to store the content of a ** single database page. The pExtra element of sqlite3_pcache_page will be ** a pointer to the szExtra bytes of extra storage that SQLite has requested ** for each entry in the page cache. ** ^{The page to be fetched is determined by the key. ^{The minimum key value ** is 1. After it has been retrieved using xFetch, the page is considered ** to be "pinned". ** ^{If the requested page is already in the page cache, then the page cache ** implementation must return a pointer to the page buffer with its content ** intact. If the requested page is not already in the cache, then the ** cache implementation should use the value of the createFlag ** parameter to help it determined what action to take: ** ^{<table border=1 width=85% align=center> ** <tr><th> createFlag </th> Behavior when page is not already in cache ** <tr><td> 0 <td> Do not allocate a new page. Return NULL. ** <tr><td> 1 <td> Allocate a new page if it easy and convenient to do so. ** ^{Otherwise return NULL. ** <tr><td> 2 <td> Make every effort to allocate a new page. Only return ** NULL if allocating a new page is effectively impossible. ** </table> ** ^{SQLite will normally invoke xFetch() with a createFlag of 0 or 1. SQLite ** will only use a createFlag of 2 after a prior call with a createFlag of 1 ** failed.)^ In between the to xFetch() calls, SQLite may ** attempt to unpin one or more cache pages by spilling the content of ** pinned pages to disk and synching the operating system disk cache. ** ^{[[the xUnpin() page cache method]] ** ^{xUnpin() is called by SQLite with a pointer to a currently pinned page ** as its second argument. If the third parameter, discard, is non-zero, ** then the page must be evicted from the cache. ** ^{If the discard parameter is ** zero, then the page may be discarded or retained at the discretion of ** page cache implementation. ^{The page cache implementation ** may choose to evict unpinned pages at any time. ** ^{The cache must not perform any reference counting. A single ** call to xUnpin() unpins the page regardless of the number of prior calls ** to xFetch(). ** ^{[[the xRekey() page cache methods]] ** ^{The xRekey() method is used to change the key value associated with the ** page passed as the second argument. If the cache ** previously contains an entry associated with newKey, it must be ** discarded. ^{Any prior cache entry associated with newKey is guaranteed not ** to be pinned. ** ^{When SQLite calls the xTruncate() method, the cache must discard all ** existing cache entries with page numbers (keys) greater than or equal ** to the value of the iLimit parameter passed to xTruncate(). If any ** of these pages are pinned, they are implicitly unpinned, meaning that ** they can be safely discarded. ** ^{[[the xDestroy() page cache method]] ** ^{The xDestroy() method is used to delete a cache allocated by xCreate(). ** All resources associated with the specified cache should be freed. ^{After ** calling the xDestroy() method, SQLite considers the [sqlite3_pcache*] ** handle invalid, and will not use it with any other sqlite3_pcache_methods2 ** functions. ** ^{[[the xShrink() page cache method]] ** ^{SQLite invokes the xShrink() method when it wants the page cache to ** free up as much of heap memory as possible. The page cache implementation ** is not obligated to free any memory, but well-behaved implementations should ** do their best.

64804. **comment:** ** CAPI3REF: Setting The Result Of An SQL Function ** METHOD: sqlite3_context ** ** These routines are used by the xFunc or xFinal callbacks that ** implement SQL functions and aggregates. See ** [sqlite3_create_function()] and [sqlite3_create_function16()] ** for additional information. *** ** These functions work very much like the [parameter binding] family of ** functions used to bind values to host parameters in prepared statements. ** Refer to the [SQL parameter] documentation for additional information. *** ** ^The sqlite3_result_blob() interface sets the result from ** an application-defined function to be the BLOB whose content is pointed ** to by the second parameter and which is N bytes long where N is the ** third parameter. *** ** ^The sqlite3_result_zeroblob(C,N) and sqlite3_result_zeroblob64(C,N) ** interfaces set the result of the application-defined function to be ** a BLOB containing all zero bytes and N bytes in size. *** ** ^The sqlite3_result_double() interface sets the result from ** an application-defined function to be a floating point value specified ** by its 2nd argument. *** ** ^The sqlite3_result_error() and sqlite3_result_error16() functions ** cause the implemented SQL function to throw an exception. *** ^SQLite uses the string pointed to by the ** 2nd parameter of sqlite3_result_error() or sqlite3_result_error16() ** as the text of an error message. ^SQLite interprets the error ** message string from sqlite3_result_error() as UTF-8. ^SQLite ** interprets the string from sqlite3_result_error16() as UTF-16 in native ** byte order. ^If the third parameter to sqlite3_result_error() ** or sqlite3_result_error16() is negative then SQLite takes as the error ** message all text up through the first zero character. ** ^If the third parameter to sqlite3_result_error() or ** sqlite3_result_error16() is non-negative then SQLite takes that many ** bytes (not characters) from the 2nd parameter as the error message. ** ^The sqlite3_result_error() and sqlite3_result_error16() ** routines make a private copy of the error message text before ** they return. Hence, the calling function can deallocate or ** modify the text after they return without harm. ** ^The sqlite3_result_error_code() function changes the error code ** returned by SQLite as a result of an error in a function. ^By default, ** the error code is SQLITE_ERROR. ^A subsequent call to sqlite3_result_error() ** or sqlite3_result_error16() resets the error code to SQLITE_ERROR. *** ** ^The sqlite3_result_error_toobig() interface causes SQLite to throw an ** error indicating that a string or BLOB is too long to represent. *** ** ^The sqlite3_result_error_nomem() interface causes SQLite to throw an ** error indicating that a memory allocation failed. *** ** ^The sqlite3_result_int() interface sets the return value ** of the application-defined function to be the 32-bit signed integer ** value given in the 2nd argument. ** ^The sqlite3_result_int64() interface sets the return value ** of the application-defined function to be the 64-bit signed integer ** value given in the 2nd argument. *** ** ^The sqlite3_result_null() interface sets the return value ** of the application-defined function to be NULL. *** ** ^The sqlite3_result_text(), sqlite3_result_text16(), ** sqlite3_result_text16e(), and sqlite3_result_text16be() interfaces ** set the return value of the application-defined function to be ** a text string which is represented as UTF-8, UTF-16 native byte order, ** UTF-16 little endian, or UTF-16 big endian, respectively. ** ^The sqlite3_result_text64() interface sets the return value of an ** application-defined function to be a text string in an encoding ** specified by the fifth (and last) parameter, which must be one ** of [SQLITE_UTF8], [SQLITE_UTF16], [SQLITE_UTF16BE], or [SQLITE_UTF16LE]. ** ^SQLite takes the text result from the application from ** the 2nd parameter of the sqlite3_result_text* interfaces. ** ^If the 3rd parameter to the sqlite3_result_text* interfaces ** is negative, then SQLite takes result text from the 2nd parameter ** through the first zero character. ** ^If the 3rd parameter to the sqlite3_result_text* interfaces ** is non-negative, then as many bytes (not characters) of the text ** pointed to by the 2nd parameter are taken as the application-defined ** function result. If the 3rd parameter is non-negative, then it ** must be the byte offset into the string where the NUL terminator would ** appear if the string were NUL terminated. If any NUL characters occur ** in the string at a byte offset that is less than the value of the 3rd ** parameter, then the resulting string will contain embedded NULs and the ** result of expressions operating on strings with embedded NULs is undefined. ** ^If the 4th parameter to the sqlite3_result_text* interfaces ** or sqlite3_result_blob is a non-NULL pointer, then SQLite calls that ** function as the destructor on the text or BLOB result when it has ** finished using that result. ** ^If the 4th parameter to the sqlite3_result_text* interfaces or to ** sqlite3_result_blob is the special constant SQLITE_STATIC, then SQLite ** assumes that the text or BLOB result is in constant space and does not ** copy the content of the parameter nor call a destructor on the content ** when it has finished using that result. ** ^If the 4th parameter to the sqlite3_result_text* interfaces ** or sqlite3_result_blob is the special constant SQLITE_TRANSIENT ** then SQLite makes a copy of the result into space obtained ** from [sqlite3_malloc()] before it returns. *** ** ^The sqlite3_result_value() interface sets the result of ** the application-defined function to be a copy of the ** [unprotected sqlite3_value] object specified by the 2nd parameter. ^The ** sqlite3_result_value() interface makes a copy of the [sqlite3_value] ** so that the [sqlite3_value] specified in the parameter may change or ** be deallocated after sqlite3_result_value() returns without harm. ** ^A [protected sqlite3_value] object may always be used where an ** [unprotected sqlite3_value] object is required, so either ** kind of [sqlite3_value] object can be used with this interface. *** ** ^The sqlite3_result_pointer(C,P,T,D) interface sets the result to an ** SQL NULL value, just like [sqlite3_result_null(C)], except that it ** also associates the host-language pointer P or type T with that ** NULL value such that the pointer can be retrieved within an ** [application-defined SQL function] using [sqlite3_value_pointer()]. ** ^If the D parameter is not NULL, then it is a pointer to a destructor ** for the P parameter. ^SQLite invokes D with P as its only argument ** when SQLite is finished with P. The T parameter should be a static ** string and preferably a string literal. The sqlite3_result_pointer() ** routine is part of the [pointer passing interface] added for SQLite 3.20.0. *** ** If these routines are called from within the different thread ** than the one containing the application-defined function that received ** the [sqlite3_context] pointer, the results are undefined.

64997. CREATE
64998. Opcode: Function P1 P2 P3 P4 P5 ** Synopsis: r[P3]=func(r[P2@P5]) *** Invoke a user function (P4 is a pointer to an sqlite3_context object that ** contains a pointer to the function to be run) with P5 arguments taken ** from register P2 and successors. The result of the function is stored ** in register P3. Register P3 must not be one of the function inputs. *** P1 is a 32-bit bitmask indicating whether or not each argument to the ** function was determined to be constant at compile time. If the first ** argument was constant then bit 0 of P1 is set. This is used to determine ** whether meta data associated with a user function argument using the ** sqlite3_set_auxdata() API may be safely retained until the next ** invocation of this opcode. *** SQL functions are initially coded as OP_Function0 with P4 pointing ** to a FuncDef object. But on first evaluation, the P4 operand is ** automatically converted into an sqlite3_context object and the operation ** changed to this OP_Function opcode. In this way, the initialization of ** the sqlite3_context object occurs only once, rather than once for each ** evaluation of the function. *** See also: Function0, AggStep, AggFinal
64999. Library used incorrectly
65000. b: p3<<28 | p5<<14 | p7 (unmasked)
65001. The format field code letter
65002. IMP: R-51513-12026 The last_insert_rowid() SQL function is a ** wrapper around the sqlite3_last_insert_rowid() C/C++ interface ** function.
65003. ** Return the value of the integer key or "rowid" for a table btree. ** This routine is only valid for a cursor that is pointing into a ** ordinary table btree. If the cursor points to an index btree or ** is invalid, the result of this routine is undefined.
65004. languageid=?
65005. Content to be checksummed
65006. Number of columns in zTab
65007. ** Return a pointer to payload information from the entry that the ** pCur cursor is pointing to. The pointer is to the beginning of ** the key if index btrees (pPage->intKey==0) and is the data for ** table btrees (pPage->intKey==1). The number of bytes of available ** key/data is written into *pAmt. If *pAmt==0, then the value ** returned will not be a valid pointer. *** This routine is an optimization. It is common for the entire key ** and data to fit on the local page and for there to be no overflow ** pages. When that is so, this routine can be used to access the ** key and data without making a copy. If the key and/or data spills ** onto overflow pages, then accessPayload() must be used to reassemble ** the key/data and copy it into a preallocated buffer. *** The pointer returned by this routine looks directly into the cached ** page of the database. The data might change or move the next time ** any btree routine is called.
65008. Number of databases with an active write-transaction ** that are candidates for a two-phase commit using a ** master-journal
65009. The bottom of the main insertion loop, if the data source ** is a SELECT statement.
65010. ** Add a whole list of operations to the operation stack. Return a ** pointer to the first operation inserted. *** Non-zero P2 arguments to jump instructions are automatically adjusted ** so that the jump target is relative to the first operation inserted.
65011. Number of prior equality constraints on same index
65012. If iPtr is another freeblock (that is, if iPtr is not the freelist ** pointer in the page header) then check to see if iStart should be ** coalesced onto the end of iPtr.
65013. A Btree handle ** ** A database connection contains a pointer to an instance of ** this object for every database file that it has open. This structure ** is opaque to the database connection. The database connection cannot ** see the internals of this structure and only deals with pointers to ** this structure. *** For some database files, the same underlying database cache might be ** shared between multiple connections. In that case, each connection ** has its own instance of this object. But each instance of this object ** points to the same BtShared object. The database cache and the ** schema associated with the database file are all contained within ** the BtShared object. *** All fields in this structure are accessed under sqlite3.mutex. ** The pBt pointer itself may not be changed while there exists cursors ** in the referenced BtShared that point back to this Btree since those ** cursors have to go through this Btree to find their BtShared and ** they often do so without holding sqlite3.mutex.
65014. Pointer to current file mapping
65015. unlock failed with an error
65016. ** This function is a wrapper around the OS specific implementation of ** sqlite3_os_init(). The purpose of the wrapper is to provide the ** ability to simulate a malloc failure, so that the handling of an ** error in sqlite3_os_init() by the upper layers can be tested.
65017. If there are now no dirty pages in the cache, set eCreate to 2. ** This is an optimization that allows sqlite3PcacheFetch() to skip ** searching for a dirty page to eject from the cache when it might ** otherwise have to.
65018. Check to see if we should honor DESC requests on index columns
65019. Pointer to sqlite3_int64 variable
65020. Average size of database rows, in pages
65021. The SELECT statement with the ORDER BY clause
65022. ** Set the EP_FromJoin property on all terms of the given expression. ** And set the Expr.iRightJoinTable to iTable for every term in the ** expression. *** ** The EP_FromJoin property is used on terms of an expression to tell ** the LEFT OUTER JOIN processing logic that this term is part of the ** join restriction specified in the ON or USING clause and not a part ** of the more general WHERE clause. These terms are moved over to the ** WHERE clause during join processing but we need to remember that they ** originated in the ON or USING clause. *** ** The Expr.iRightJoinTable tells the WHERE clause processing that the ** expression depends on table iRightJoinTable even if that table is not ** explicitly mentioned in the expression. That information is needed ** for cases like this: *** ** SELECT * FROM t1 LEFT JOIN t2 ON t1.a=t2.b AND t1.x=5 ** ** The where clause needs to defer the handling of the t1.x=5 ** term until after the t2 loop of the join. In that way, a ** NULL t2 row will be inserted whenever t1.x!=5. If we do not ** defer the handling of t1.x=5, it will be processed immediately ** after the t1 loop and rows with t1.x!=5 will never appear in ** the output, which is incorrect.
65023. 324
65024. .eSubtype =
65025. ** Create a new cursor for the BTREE whose root is on the page ** iTable. If a read-only cursor is requested, it is assumed that ** the caller already has at least a read-only transaction open ** on the database already. If a write-cursor is requested, then ** the caller is assumed to have an open write transaction. *** ** If the BTREE_WRCR bit of wrFlag is clear, then the cursor can only ** be used for reading. If the BTREE_WRCR bit is set, then the cursor ** can be used for reading or for writing if other conditions for writing ** are also met. These are the conditions that must be met in order ** for writing to be allowed: *** ** 1: The cursor must have been opened with wrFlag containing BTREE_WRCR *** ** 2: Other database connections that share the same pager cache ** but which are not in the READ_UNCOMMITTED state may not have ** cursors open with wrFlag==0 on the same table. Otherwise ** the changes made by this write cursor would be visible to ** the read cursors in the other database connection. *** ** 3: The database must be writable (not on read-only media) *** ** 4: There must be an active transaction. *** ** The BTREE_FORDELETE bit of wrFlag may optionally be set if BTREE_WRCR ** is set. If FORDELETE is set, that is a hint to the implementation that ** this cursor will only be used to seek to and delete entries of an index ** as part of a larger DELETE statement. The FORDELETE hint is not used by ** this implementation. But in a hypothetical alternative storage engine ** in which index entries are automatically deleted when corresponding table ** rows are deleted, the FORDELETE flag is a hint that all SEEK and DELETE ** operations on this cursor can be no-ops and all READ operations can ** return a null row (2-bytes: 0x01 0x00). *** ** No checking is done to make sure that page iTable really is the ** root page of a b-tree. If it is not, then the cursor acquired ** will not work correctly. *** ** It is assumed that the sqlite3BtreeCursorZero() has been called ** on pCur to initialize the memory space prior to invoking this routine.

65114. Buffer containing leaf data

65115. Zero out anything following *ppList

65116. Opcode: SeekRowid P1 P2 P3 * * * Synopsis: intkey=r[P3] ** P1 is the index of a cursor open on an SQL table btree (with integer ** keys). If register P3 does not contain an integer or if P1 does not ** contain a record with rowid P3 then jump immediately to P2. ** Or, if P2 is 0, raise an SQLITE_CORRUPT error. If P1 does contain ** a record with rowid P3 then ** leave the cursor pointing at that record and fall through to the next ** instruction. *** The OP_NotExists opcode performs the same operation, but with OP_NotExists ** the P3 register must be guaranteed to contain an integer value. With this ** opcode, register P3 might not contain an integer. *** The OP_NotFound opcode performs the same operation on index btrees ** (with arbitrary multi-value keys). *** This opcode leaves the cursor in a state where it cannot be advanced ** in either direction. In other words, the Next and Prev opcodes will ** not work following this opcode. *** See also: Found, NotFound, NoConflict, SeekRowid

65117. SQLITE_ALTER_TABLE

65118. ** Many system calls are accessed through pointer-to-functions so that ** they may be overridden at runtime to facilitate fault injection during ** testing and sandboxing. The following array holds the names and pointers ** to all overrideable system calls.

65119. Number of extra registers to allocate

65120. **comment:** ** Generate the beginning of the loop used for WHERE clause processing. ** The return value is a pointer to an opaque structure that contains ** information needed to terminate the loop. Later, the calling routine ** should invoke sqlite3WhereEnd() with the return value of this function ** in order to complete the WHERE clause processing. ** If an error occurs, this routine returns NULL. ** The basic idea is to do a nested loop, one loop for each table in ** the FROM clause of a select. (INSERT and UPDATE statements are the ** same as a SELECT with only a single table in the FROM clause.) For ** example, if the SQL is this: ** ** SELECT * FROM t1, t2, t3 WHERE ...; ** ** Then the code generated is conceptually like the following: ** ** foreach row1 in t1 do \
Code generated ** foreach row2 in t2 do -- by sqlite3WhereBegin() ** foreach row3 in t3 do / ** ... ** end \ Code generated ** end |-- by sqlite3WhereEnd() ** end / ** ** Note that the loops might not be nested in the order in which they ** appear in the FROM clause if a different order is better able to make ** use of indices. Note also that when the IN operator appears in ** the WHERE clause, it might result in additional nested loops for ** scanning through all values on the right-hand side of the IN. ** ** There are Btree cursors associated with each table. t1 uses cursor ** number pTabList->a[0].iCursor. t2 uses the cursor pTabList->a[1].iCursor. ** And so forth. This routine generates code to open those VDBE cursors ** and sqlite3WhereEnd() generates the code to close them. ** ** The code that sqlite3WhereBegin() generates leaves the cursors named ** in pTabList pointing at their appropriate entries. The [...] code ** can use OP_Column and OP_Rowid opcodes on these cursors to extract ** data from the various tables of the loop. ** ** If the WHERE clause is empty, the foreach loops must each scan their ** entire tables. Thus a three-way join is an O(N^3) operation. But if ** the tables have indices and there are terms in the WHERE clause that ** refer to those indices, a complete table scan can be avoided and the ** code will run much faster. Most of the work of this routine is checking ** to see if there are indices that can be used to speed up the loop. ** ** Terms of the WHERE clause are also used to limit which rows actually ** make it to the "..." in the middle of the loop. After each "foreach", ** terms of the WHERE clause that use only terms in that loop and outer ** loops are evaluated and if false a jump is made around all subsequent ** inner loops (or around the "..." if the test occurs within the inner- ** most loop) *** OUTER JOINS ** ** An outer join of tables t1 and t2 is conceptually coded as follows: ** ** foreach row1 in t1 do ** flag = 0 ** foreach row2 in t2 do ** start: ** ... ** flag = 1 ** end ** if flag==0 then ** move the row2 cursor to a null row ** goto start ** fi ** end ** ** ORDER BY CLAUSE PROCESSING ** ** pOrderBy is a pointer to the ORDER BY clause (or the GROUP BY clause ** if the WHERE_GROUPBY flag is set in wctrlFlags) of a SELECT statement ** if there is one. If there is no ORDER BY clause or if this routine ** is called from an UPDATE or DELETE statement, then pOrderBy is NULL. ** ** The iIdxCur parameter is the cursor number of an index. If ** WHERE_OR_SUBCLAUSE is set, iIdxCur is the cursor number of an index ** to use for OR clause processing. The WHERE clause should use this ** specific cursor. If WHERE_ONEPASS_DESIRED is set, then iIdxCur is ** the first cursor in an array of cursors for all indices. iIdxCur should ** be used to compute the appropriate cursor depending on which index is ** used.

65132. ** An rtree virtual-table object.
65133. Search strategy (see below)
65134. pPage is a leaf node. This loop navigates the cursor so that it ** points to the first interior cell that it points to the parent of ** the next page in the tree that has not yet been visited. The ** pCur->aiIdx[pCur->iPage] value is set to the index of the parent cell ** of the page, or to the number of cells in the page if the next page ** to visit is the right-child of its parent. *** If all pages in the tree have been visited, return SQLITE_OK to the ** caller.
65135. 278
65136. increment the cell count
65137. TEXT
65138. Non-zero if an error has occurred
65139. Number of PMAs to read
65140. Bytes of prefix compression for term
65141. Newly allocated session object
65142. xRename
65143. Table containing the REFERENCES clause (aka: Child)
65144. Name of the table into which we insert
65145. If either of the sqlite3_blob_open() or sqlite3_blob_reopen() calls ** above returned SQLITE_ERROR, return SQLITE_CORRUPT_VTAB instead. ** All the reasons those functions might return SQLITE_ERROR - missing ** table, missing row, non-blob/text in block column - indicate ** backing store corruption.
65146. ** This section provides definitions to allow the ** FTS3 extension to be compiled outside of the ** amalgamation.
65147. New object
65148. Counter variable
65149. 220
65150. ** Macros determining the rowids used by segment leaves and dlidx leaves ** and nodes. All nodes and leaves are stored in the %_data table with large ** positive rowids. *** Each segment has a unique non-zero 16-bit id. *** The rowid for each segment leaf is found by passing the segment id and ** the leaf page number to the FTS5_SEGMENT_ROWID macro. Leaves are numbered ** sequentially starting from 1.
65151. 27
65152. synopsis: r[P2]=parameter(P1,P4)
65153. **comment:** ** The pointer map is a lookup table that identifies the parent page for ** each child page in the database file. The parent page is the page that ** contains a pointer to the child. Every page in the database contains ** 0 or 1 parent pages. (In this context 'database page' refers ** to any page that is not part of the pointer map itself.) Each pointer map ** entry consists of a single byte 'type' and a 4 byte parent page number. ** The PTRMAP_XXX identifiers below are the valid types. *** The purpose of the pointer map is to facilitate moving pages from one ** position in the file to another as part of autovacuum. When a page ** is moved, the pointer in its parent must be updated to point to the ** new location. The pointer map is used to locate the parent page quickly. ***
PTRMAP_ROOTPAGE: The database page is a root-page. The page-number is not ** used in this case. *** PTRMAP_FREEPAGE: The database page is an unused (free) page. The page-number ** is not used in this case. *** PTRMAP_OVERFLOW1: The database page is the first page in a list of ** overflow pages. The page number identifies the page that ** contains the cell with a pointer to this overflow page. *** PTRMAP_OVERFLOW2: The database page is the second or later page in a list of ** overflow pages. The page-number identifies the previous ** page in the overflow page list. *** PTRMAP_BTREE: The database page is a non-root btree page. The page number ** identifies the parent page in the btree.
label: code-design
65154. The following line of code (and the "p++" below the while() loop) is ** normally all that is required to move pointer p to the desired ** position. The exception is if this node is being loaded from disk ** incrementally and pointer "p" now points to the first byte past ** the populated part of pReader->aNode[].
65155. synopsis: iDb=P1 root=P2 write=P3
65156. ** INSERT STACK UNION HERE **

65188. xEof
65189. Init nFree to non-freeblock free space
65190. 128
65191. True if read-only
65192. This routine is just a convenient place to set a breakpoint that will ** fire after each opcode is inserted and displayed using ** "PRAGMA vdbe_addoptrace=on".
65193. If control flows to this point, then it was not possible to add the ** page being freed as a leaf page of the first trunk in the free-list. ** Possibly because the free-list is empty, or possibly because the ** first trunk in the free-list is full. Either way, the page being freed ** will become the new first trunk page in the free-list.

65194. Array of nodes containing the parse
65195. The opcode to be commented
65196. ** When this function is called, *ppPoslist is assumed to point to the ** start of a position-list. After it returns, *ppPoslist points to the ** first byte after the position-list. *** A position list is list of positions (delta encoded) and columns for ** a single document record of a doclist. So, in other words, this ** routine advances *ppPoslist so that it points to the next docid in ** the doclist, or to the first byte past the end of the doclist. *** If pp is not NULL, then the contents of the position list are copied ** to *pp. *pp is set to point to the first byte past the last byte copied ** before this function returns.
65197. Overwrite the old cell with the new if they are the same size. ** We could also try to do this if the old cell is smaller, then add ** the leftover space to the free list. But experiments show that ** doing that is no faster than skipping this optimization and just ** calling dropCell() and insertCell(). *** This optimization cannot be used on an autovacuum database if the ** new entry uses overflow pages, as the insertCell() call below is ** necessary to add the PTRMAP_OVERFLOW1 pointer-map entry.
65198. Figure out the size of the output
65199. Restore the original value of db->flags
65200. A pending-terms seg-reader for an FTS4 table that uses order=desc. ** Pending-terms doclists are always built up in ascending order, so ** we have to iterate through them backwards here.
65201. ** Combinations of two or more EP_* flags
65202. ** CAPI3REF: Fundamental Datatypes ** KEYWORDS: SQLITE_TEXT *** ^ (Every value in SQLite has one of five fundamental datatypes: ** ** ** 64-bit signed integer ** 64-bit IEEE floating point number ** string ** BLOB ** NULL **)*** These constants are codes for each of those types. *** Note that the SQLITE_TEXT constant was also used in SQLite version 2 ** for a completely different meaning. Software that links against both ** SQLite version 2 and SQLite version 3 should use SQLITE3_TEXT, not ** SQLITE_TEXT.
65203. Do any ON CASCADE, SET NULL or SET DEFAULT operations required to ** handle rows (possibly in other tables) that refer via a foreign key ** to the row just deleted.
65204. Set if thread is finished but not joined
65205. The complete WHERE clause
65206. Array to sort entries of
65207. '@', '#', '!'. Alphabetic SQL variables
65208. Now check that the iter.nEmpty leaves following the current leaf ** (a) exist and (b) contain no terms.
65209. ** End of the special code for wince *****
65210. The aArg[] array needs to grow.
65211. Hash of the name
65212. An instance of the IdxExprTrans object carries information about a ** mapping from an expression on table columns into a column in an index ** down through the Walker.
65213. If we reach this point, that means it is OK to perform the transformation
65214. Cell pCell is destined for new sibling page pNew. Originally, it ** was either part of sibling page iOld (possibly an overflow cell), ** or else the divider cell to the left of sibling page iOld. So, ** if sibling page iOld had the same page number as pNew, and if ** pCell really was a part of sibling page iOld (not a divider or ** overflow cell), we can skip updating the pointer map entries.
65215. Deal with as much of this write request as possible by transferring ** data from the memory mapping using memcpy().
65216. **comment:** TODO: Check that zTarget and zRbu are non-NULL
 label: requirement
65217. If not NULL, info on how to process DISTINCT
65218. Table we are trying to access
65219. Set up appropriate ctrlFlags
65220. **comment:** ** This function is called when initializing an FTS4 table that uses the ** content=xxx option. It determines the number of and names of the columns ** of the new FTS4 table. *** The third argument passed to this function is the value passed to the ** config=xxx option (i.e. "xxx"). This function queries the database for ** a table of that name. If found, the output variables are populated ** as follows: *** *pnCol: Set to the number of columns table xxx has, *** *pnStr: Set to the total amount of space required to store a copy ** of each columns name, including the nul-terminator. *** *pazCol: Set to point to an array of *pnCol strings. Each string is ** the name of the corresponding column in table xxx. The array ** and its contents are allocated using a single allocation. It ** is the responsibility of the caller to free this allocation ** by eventually passing the *pazCol value to sqlite3_free(). *** If the table cannot be found, an error code is returned and the output ** variables are undefined. Or, if an OOM is encountered, SQLITE_NOMEM is ** returned (and the output variables are undefined).

65612. IMP: R-22934-25134

65613. ***** End of fts3.h *****

65614. ** Move the page pPg to location pgno in the file. *** There must be no references to the page previously located at ** pgno (which we call pPgOld) though that page is allowed to be ** in cache. If the page previously located at pgno is not already ** in the rollback journal, it is not put there by this routine. *** ** References to the page pPg remain valid. Updating any ** meta-data associated with pPg (i.e. data stored in the nExtra bytes ** allocated along with the page) is the responsibility of the caller. *** A transaction must be active when this routine is called. It used to be ** required that a statement transaction was not active, but this restriction ** has been removed (CREATE INDEX needs to move a page when a statement ** transaction is active). *** If the fourth argument, isCommit, is non-zero, then this page is being ** moved as part of a database reorganization just before the transaction ** is being committed. In this case, it is guaranteed that the database page ** pPg refers to will not be written to again within this transaction. *** This function may return SQLITE_NOMEM or an IO error code if an error ** occurs. Otherwise, it returns SQLITE_OK.

65615. If the file was successfully opened for read/write access, ** choose a default page size in case we have to create the ** database file. The default page size is the maximum of: ** + SQLITE_DEFAULT_PAGE_SIZE, ** + The value returned by sqlite3OsSectorSize() ** + The largest page size that can be written atomically.

65616. iLevel value for root of the tree

65617. **comment:** ** CAPI3REF: Unlock Notification ** METHOD: sqlite3 *** ^When running in shared-cache mode, a database operation may fail with ** an [SQLITE_LOCKED] error if the required locks on the shared-cache or ** individual tables within the shared-cache cannot be obtained. See ** [SQLite Shared-Cache Mode] for a description of shared-cache locking. ** ^This API may be used to register a callback that SQLite will invoke ** when the connection currently holding the required lock relinquishes it. ** ^This API is only available if the library was compiled with the ** [SQLITE_ENABLE_UNLOCK_NOTIFY] C-preprocessor symbol defined. *** See Also: [Using the SQLite Unlock Notification Feature]. *** ^Shared-cache locks are released when a database connection concludes ** its current transaction, either by committing it or rolling it back. *** ^When a connection (known as the blocked connection) fails to obtain a ** shared-cache lock and SQLITE_LOCKED is returned to the caller, the ** identity of the database connection (the blocking connection) that ** has locked the required resource is stored internally. ^After an ** application receives an SQLITE_LOCKED error, it may call the ** sqlite3_unlock_notify() method with the blocked connection handle as ** the first argument to register for a callback that will be invoked ** when the blocking connections current transaction is concluded. ^The ** callback is invoked from within the [sqlite3_step] or [sqlite3_close] ** call that concludes the blocking connections transaction. *** ^If sqlite3_unlock_notify() is called in a multi-threaded application, ** there is a chance that the blocking connection will have already ** concluded its transaction by the time sqlite3_unlock_notify() is invoked. ** If this happens, then the specified callback is invoked immediately, ** from within the call to sqlite3_unlock_notify().)^** ** ^If the blocked connection is attempting to obtain a write-lock on a ** shared-cache table, and more than one other connection currently holds ** a read-lock on the same table, then SQLite arbitrarily selects one of ** the other connections to use as the blocking connection. *** ** ^There may be at most one unlock-notify callback registered by a ** blocked connection. If sqlite3_unlock_notify() is called when the ** blocked connection already has a registered unlock-notify callback, ** then the new callback replaces the old.^** ^If sqlite3_unlock_notify() is ** called with a NULL pointer as its second argument, then any existing ** unlock-notify callback is canceled. ^The blocked connections ** unlock-notify callback may also be canceled by closing the blocked ** connection using [sqlite3_close]. *** ^The unlock-notify callback is not reentrant. If an application invokes ** any sqlite3_xxx API functions from within an unlock-notify callback, a ** crash or deadlock may be the result. *** ** ^Unless deadlock is detected (see below), sqlite3_unlock_notify() always ** returns SQLITE_OK. *** Callback Invocation Details *** When an unlock-notify callback is registered, the application provides a ** single void* pointer that is passed to the callback when it is invoked. ** However, the signature of the callback function allows SQLite to pass ** it an array of void* context pointers. The first argument passed to ** an unlock-notify callback is a pointer to an array of void* pointers, ** and the second is the number of entries in the array. *** When a blocking connections transaction is concluded, there may be ** more than one blocked connection that has registered for an unlock-notify ** callback. ^If two or more such blocked connections have specified the ** same callback function, then instead of invoking the callback function ** multiple times, it is invoked once with the set of void* context pointers ** specified by the blocked connections bundled together into an array. ** This gives the application an opportunity to prioritize any actions ** related to the set of unblocked database connections. *** Deadlock Detection *** Assuming that after registering for an unlock-notify callback a ** database waits for the callback to be issued before taking any further ** action (a reasonable assumption), then using this API may cause the ** application to deadlock. For example, if connection X is waiting for ** connection Y's transaction to be concluded, and similarly connection ** Y is waiting on connection X's transaction, then neither connection ** will proceed and the system may remain deadlocked indefinitely. *** To avoid this scenario, the sqlite3_unlock_notify() performs deadlock ** detection. ^If a given call to sqlite3_unlock_notify() would put the ** system in a deadlocked state, then SQLITE_LOCKED is returned and no ** unlock-notify callback is registered. The system is said to be in ** a deadlocked state if connection A has registered for an unlock-notify ** callback on the conclusion of connection B's transaction, and connection ** B has itself registered for an unlock-notify callback when connection ** A's transaction is concluded. ^Indirect deadlock is also detected, so ** the system is also considered to be deadlocked if connection B has ** registered for an unlock-notify callback on the conclusion of connection ** C's transaction, where connection C is waiting on connection A. ^Any ** number of levels of indirection are allowed. *** The "DROP TABLE" Exception *** When a call to [sqlite3_step()] returns SQLITE_LOCKED, it is almost ** always appropriate to call sqlite3_unlock_notify(). There is however, ** one exception. When executing a "DROP TABLE" or "DROP INDEX" statement, ** SQLite checks if there are any currently executing SELECT statements ** that belong to the same connection. If there are, SQLITE_LOCKED is ** returned. In this case there is no "blocking connection", so invoking ** sqlite3_unlock_notify() results in the unlock-notify callback being ** invoked immediately. If the application then re-attempts the "DROP TABLE" ** or "DROP INDEX" query, an infinite loop might be the result. *** One way around this problem is to check the extended error code returned ** by an sqlite3_step() call. ^If there is a blocking connection, then the ** extended

error code is set to SQLITE_LOCKED_SHAREDCACHE. Otherwise, in ** the special "DROP TABLE/INDEX" case, the extended error code is just **
SQLITE_LOCKED.)^

65738. ** CAPI3REF: Initialize The SQLite Library *** ^The sqlite3_initialize() routine initializes the ** SQLite library. ^The sqlite3_shutdown() routine ** deallocates any resources that were allocated by sqlite3_initialize(). ** These routines are designed to aid in process initialization and ** shutdown on embedded systems. Workstation applications using ** SQLite normally do not need to invoke either of these routines. *** A call to sqlite3_initialize() is an "effective" call if it is ** the first time sqlite3_initialize() is invoked during the lifetime of ** the process, or if it is the first time sqlite3_initialize() is invoked ** following a call to sqlite3_shutdown(). ^Only an effective call ** of sqlite3_initialize() does any initialization. All other calls ** are harmless no-ops.)^ *** A call to sqlite3_shutdown() is an "effective" call if it is the first ** call to sqlite3_shutdown() since the last sqlite3_initialize(). ^Only ** an effective call to sqlite3_shutdown() does any deinitialization. ** All other valid calls to sqlite3_shutdown() are harmless no-ops.)^ *** The sqlite3_initialize() interface is threadsafe, but sqlite3_shutdown() ** is not. The sqlite3_shutdown() interface must only be called from a ** single thread. All open [database connections] must be closed and all ** other SQLite resources must be deallocated prior to invoking ** sqlite3_shutdown(). *** Among other things, ^sqlite3_initialize() will invoke ** sqlite3_os_init(). Similarly, ^sqlite3_shutdown() ** will invoke sqlite3_os_end(). *** ^The sqlite3_initialize() routine returns [SQLITE_OK] on success. *** ^If for some reason, sqlite3_initialize() is unable to initialize ** the library (perhaps it is unable to allocate a needed resource such ** as a mutex) it returns an [error code] other than [SQLITE_OK]. *** ^The sqlite3_initialize() routine is called internally by many other ** SQLite interfaces so that an application usually does not need to ** invoke sqlite3_initialize() directly. For example, [sqlite3_open()] ** calls sqlite3_initialize() so the SQLite library will be automatically ** initialized when [sqlite3_open()] is called if it has not been initialized ** already. ^However, if SQLite is compiled with the [SQLITE_OMIT_AUTOINIT] ** compile-time option, then the automatic calls to sqlite3_initialize() ** are omitted and the application must call sqlite3_initialize() directly ** prior to using any other SQLite interface. For maximum portability, ** it is recommended that applications always invoke sqlite3_initialize() ** directly prior to using any other SQLite interface. Future releases ** of SQLite may require this. In other words, the behavior exhibited ** when SQLite is compiled with [SQLITE_OMIT_AUTOINIT] might become the ** default behavior in some future release of SQLite. *** ^The sqlite3_os_init() routine does operating-system specific ** initialization of the SQLite library. The sqlite3_os_end() ** routine undoes the effect of sqlite3_os_init(). Typical tasks ** performed by these routines include allocation or deallocation ** of static resources, initialization of global variables, ** setting up a default [sqlite3_vfs] module, or setting up ** a default configuration using [sqlite3_config()]. *** ^The application should never invoke either sqlite3_os_init() ** or sqlite3_os_end() directly. The application should only invoke ** sqlite3_initialize() and sqlite3_shutdown(). The sqlite3_os_init() ** interface is called automatically by sqlite3_initialize() and ** sqlite3_os_end() is called by sqlite3_shutdown(). Appropriate ** implementations for sqlite3_os_init() and sqlite3_os_end() ** are built into SQLite when it is compiled for Unix, Windows, or OS/2. ** When [custom builds | built for other platforms] ** (using the [SQLITE_OS_OTHER=1] compile-time ** option) the application must supply a suitable implementation for ** sqlite3_os_init() and sqlite3_os_end(). An application-supplied ** implementation of sqlite3_os_init() or sqlite3_os_end() ** must return [SQLITE_OK] on success and some other [error code] upon ** failure.

66135. ** Allowed values for sqlite3_rtree_query.eWithin and .eParentWithin.

66136. Characters. %c

66137. ** Add all WhereLoop objects for a single table of the join where the table ** is identified by pBuilder->pNew->iTab. That table is guaranteed to be ** a b-tree table, not a virtual table. *** The costs (WhereLoop.rRun) of the b-tree loops added by this function ** are calculated as follows: *** For a full scan, assuming the table (or index) contains nRow rows: *** cost = nRow * 3.0 // full-table scan ** cost = nRow * K // scan of covering index ** cost = nRow * (K+3.0) // scan of non-covering index *** where K is a value between 1.1 and 3.0 set based on the relative ** estimated average size of the index and table records. *** For an index scan, where nVisit is the number of index rows visited ** by the scan, and nSeek is the number of seek operations required on ** the index b-tree: *** cost = nSeek * (log(nRow) + K * nVisit) // covering index ** cost = nSeek * (log(nRow) + (K+3.0) * nVisit) // non-covering index *** Normally, nSeek is 1. nSeek values greater than 1 come about if the ** WHERE clause includes "x IN (...) terms used in place of "x=?". Or when ** implicit "x IN (SELECT x FROM tbl)" terms are added for skip-scans. *** The estimated values (nRow, nVisit, nSeek) often contain a large amount ** of uncertainty. For this reason, scoring is designed to pick plans that ** "do the least harm" if the estimates are inaccurate. For example, a ** log(nRow) factor is omitted from a non-covering index scan in order to ** bias the scoring in favor of using an index, since the worst-case ** performance of using an index is far better than the worst-case performance ** of a full table scan.

66138. **comment:** ** An instance of the following object records the location of ** each unused scratch buffer.

66335. Total size of iBestCol in tokens
66336. ** Attempt to set a system-lock on the file pFile. The lock is ** described by pLock. *** If the pFile was opened read/write from unix-excl, then the only lock ** ever obtained is an exclusive lock, and it is obtained exactly once ** the first time any lock is attempted. All subsequent system locking ** operations become no-ops. Locking operations still happen internally, ** in order to coordinate access between separate database connections ** within this process, but all of that is handled in memory and the ** operating system does not participate. *** This function is a pass-through to fcntl(F_SETLK) if pFile is using ** any VFS other than "unix-excl" or if pFile is opened on "unix-excl" ** and is read-only. *** Zero is returned if the call completes successfully, or -1 if a call ** to fcntl() fails. In this case, errno is set appropriately (by fcntl()).
66337. Error condition
66338. **comment:** ** Add a new name/number pair to a VList. This might require that the ** VList object be reallocated, so return the new VList. If an OOM ** error occurs, the original VList returned and the ** db->mallocFailed flag is set. *** A VList is really just an array of integers. To destroy a VList, ** simply pass it to sqlite3DbFree(). *** The first integer is the number of integers allocated for the whole ** VList. The second integer is the number of integers actually used. ** Each name/number pair is encoded by subsequent groups of 3 or more ** integers. *** Each name/number pair starts with two integers which are the numeric ** value for the pair and the size of the name/number pair, respectively. ** The text name overlays one or more following integers. The text name ** is always zero-terminated. *** Conceptually: *** struct VList { ** int nAlloc; // Number of allocated slots ** int nUsed; // Number of used slots ** struct VListEntry { ** int iValue; // Value for this entry ** int nSlot; // Slots used by this entry ** ... variable name goes here ** } a[0]; ** } *** During code generation, pointers to the variable names within the ** VList are taken. When that happens, nAlloc is set to zero as an ** indication that the VList may never again be enlarged, since the ** accompanying realloc() would invalidate the pointers.

66453. **comment:** ** This routine is called to handle SQL of the following forms: ** ** insert into TABLE (IDLIST) values(EXPRLIST),(EXPRLIST),... ** insert into TABLE (IDLIST) select ** insert into TABLE (IDLIST) default values ** ** The IDLIST following the table name is always optional. If omitted, ** then a list of all (non-hidden) columns for the table is substituted. ** The IDLIST appears in the pColumn parameter. pColumn is NULL if IDLIST ** is omitted. ** ** For the pSelect parameter holds the values to be inserted for the ** first two forms shown above. A VALUES clause is really just short-hand ** for a SELECT statement that omits the FROM clause and everything else ** that follows. If the pSelect parameter is NULL, that means that the ** DEFAULT VALUES form of the INSERT statement is intended. ** ** The code generated follows one of four templates. For a simple ** insert with data coming from a single-row VALUES clause, the code executes ** once straight down through. Pseudo-code follows (we call this ** the "1st template"): ** ** open write cursor to <table> and its indices ** put VALUES clause expressions into registers ** write the resulting record into <table> ** cleanup ** ** The three remaining templates assume the statement is of the form ** ** INSERT INTO <table> SELECT ... ** ** If the SELECT clause is of the restricted form "SELECT * FROM <table2>" - ** in other words if the SELECT pulls all columns from a single table ** and there is no WHERE or LIMIT or GROUP BY or ORDER BY clauses, and ** if <table2> and <table1> are distinct tables but have identical ** schemas, including all the same indices, then a special optimization ** is invoked that copies raw records from <table2> over to <table1>. ** See the xferOptimization() function for the implementation of this ** template. This is the 2nd template. ** ** open a write cursor to <table> ** open read cursor on <table2> ** transfer all records in <table2> over to <table> ** close cursors ** foreach index on <table> ** open a write cursor on the <table> index ** open a read cursor on the corresponding <table2> index ** transfer all records from the read to the write cursors ** close cursors ** end foreach ** ** The 3rd template is for when the second template does not apply ** and the SELECT clause does not read from <table> at any time. ** The generated code follows this template: ** ** X <- A ** goto B ** A: setup for the SELECT ** loop over the rows in the SELECT ** load values into registers R..R+n ** yield X ** end loop ** cleanup after the SELECT ** end-coroutine X ** B: open write cursor to <table> and its indices ** C: yield X, at EOF goto D ** insert the select result into <table> from R..R+n ** goto C ** D: cleanup ** ** The 4th template is used if the insert statement takes its ** values from a SELECT but the data is being inserted into a table ** that is also read as part of the SELECT. In the third form, ** we have to use an intermediate table to store the results of ** the select. The template is like this: ** ** X <- A ** goto B ** A: setup for the SELECT ** loop over the tables in the SELECT ** load value into register R..R+n ** yield X ** end loop ** cleanup after the SELECT ** end co-routine R ** B: open temp table ** L: yield X, at EOF goto M ** insert row from R..R+n into temp table ** goto L ** M: open write cursor to <table> and its indices ** rewind temp table ** C: loop over rows of intermediate table ** transfer values from intermediate table into <table> ** end loop ** D: cleanup

66535. This loop determines (a) if the commit hook should be invoked and ** (b) how many database files have open write transactions, not ** including the temp database. (b) is important because if more than ** one database file has an open write transaction, a master journal ** file is required for an atomic commit.
66536. stmt_cursor is a subclass of sqlite3_vtab_cursor which will ** serve as the underlying representation of a cursor that scans ** over rows of the result
66537. The minor type of the error token
66538. Destructor for the data
66539. Database is open
66540. IN/OUT: Pointer to PendingList struct
66541. If the column has REAL affinity, it may currently be stored as an ** integer. Use OP_RealAffinity to make sure it is really real. *** EVIDENCE-OF: R-60985-57662 SQLite will convert the value back to ** floating point when extracting it from the record.
66542. ** Are most of the Win32 Unicode APIs available (i.e. with certain exceptions ** based on the sub-platform)?
66543. Report an out-of-memory (OOM) condition
66544. Make sure initialized even if FullPathname() fails
66545. trigger_event ::= UPDATE
66546. A
66547. If the entry in aPgno[] is already set, then the previous writer ** must have exited unexpectedly in the middle of a transaction (after ** writing one or more dirty pages to the WAL to free up memory). ** Remove the remnants of that writers uncommitted transaction from ** the hash-table before writing any new entries.
66548. Assert that the mutex (if any) associated with the BtShared database ** that contains table p is held by the caller. See header comments ** above function sqlite3VtabUnlockList() for an explanation of why ** this makes it safe to access the sqlite3.pDisconnect list of any ** database connection that may have an entry in the p->pVTable list.
66549. amalgamator: keep
66550. ** 2008 October 07 *** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** May you do good and not evil.
** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This file contains the C functions that implement mutexes. ***
This implementation in this file does not provide any mutual ** exclusion and is thus suitable for use only in applications ** that use SQLite in a single thread. The routines defined ** here are place-holders. Applications can substitute working ** mutex routines at start-time using the ***
sqlite3_config(SQLITE_CONFIG_MUTEX,...) *** interface. *** If compiled with SQLITE_DEBUG, then additional logic is inserted ** that does error checking on mutexes to make sure they are being ** called correctly.
66551. Opcode: Compare P1 P2 P3 P4 P5 ** Synopsis: r[P1@P3] <-> r[P2@P3] ** ** Compare two vectors of registers in reg(P1)..reg(P1+P3-1) (call this ** vector "A") and in reg(P2)..reg(P2+P3-1) ("B"). Save the result of ** the comparison for use by the next OP_Jump instruct. *** If P5 has the OPFLAG_PERMUTE bit set, then the order of comparison is ** determined by the most recent OP_Permutation operator. If the ** OPFLAG_PERMUTE bit is clear, then register are compared in sequential ** order. *** P4 is a KeyInfo structure that defines collating sequences and sort ** orders for the comparison. The permutation applies to registers ** only. The KeyInfo elements are used sequentially. *** The comparison is a sort comparison, so NULLs compare equal, ** NULLs are less than numbers, numbers are less than strings, ** and strings are less than blobs.
66552. Page size according to the log
66553. ** Lock the file with the lock specified by parameter locktype - one ** of the following: *** (1) SHARED_LOCK ** (2) RESERVED_LOCK ** (3)
PENDING_LOCK ** (4) EXCLUSIVE_LOCK *** Sometimes when requesting one lock state, additional lock states ** are inserted in between. The locking might fail on one of the later ** transitions leaving the lock state different from what it started but ** still short of its goal. The following chart shows the allowed ** transitions and the inserted intermediate states: *** UNLOCKED -> SHARED ** SHARED -> RESERVED ** SHARED -> (PENDING) -> EXCLUSIVE
** RESERVED -> (PENDING) -> EXCLUSIVE ** PENDING -> EXCLUSIVE *** This routine will only increase a lock. The winUnlock() routine ** erases all locks at once and returns us immediately to locking level 0. ** It is not possible to lower the locking level one step at a time. You ** must go straight to locking level 0.
66554. OUT: Pointer to position list
66555. Make sure a mutex is held on the table to be accessed
66556. setlist
66557. Check if there exists a MATCH constraint - even an unusable one. If there ** is, do not consider the lookup-by-rowid plan as using such a plan would ** require the VDBE to evaluate the MATCH constraint, which is not currently ** possible.
66558. Check to see if the new rowid already exists in the table. Skip ** the following conflict logic if it does not.
66559. Remove the shared lock before trying the range. we'll need to ** reestablish the shared lock if we can't get the afpUnlock
66560. If only SQLITE_ENABLE_STAT3_OR_STAT4 is on, then the largest input ** possible to this routine is 310, resulting in a maximum x of 31
66561. 232
66562. ** The second argument, argv[], is an array of pointers to nul-terminated ** strings. This function makes a copy of the array and strings into a ** single block of memory. It then dequotes any of the strings that appear ** to be quoted. *** If successful, output parameter *pazDequote is set to point at the ** array of dequoted strings and SQLITE_OK is returned. The caller is ** responsible for eventually calling sqlite3_free() to free the array ** in this case. Or, if an error occurs, an SQLite error code is returned. ** The final value of *pazDequote is undefined in this case.
66563. ATTACH
66564. Temp space for PoslistNearMerge()
66565. True if the GROUP BY and ORDER BY are the same
66566. ** Allocate VdbeCursor number iCur. Return a pointer to it. Return NULL ** if we run out of memory.
66567. Conflict algorithm. (OE_Abort, etc)
66568. (272) input ::= cmdlist
66569. Generate code for an unconditional jump to instruction iDest
66570. CSE1 from below
66571. Set the threshold at which OP_Once counters reset back to zero. ** By default this is 0x7fffffff (over 2 billion), but that value is ** too big to test in a reasonable amount of time, so this control is ** provided to set a small and easily reachable reset value.
66572. Root page number of the table to be locked
66573. a short read or version format mismatch means we need to create a new ** conch file.
66574. ** Try to read the wal-index header. Return 0 on success and 1 if ** there is a problem. *** The wal-index is in shared memory. Another thread or process might ** be writing the header at the same time this procedure is trying to ** read it, which might result in inconsistency. A dirty read is detected ** by verifying that both copies of the header are the same and also by ** a checksum on the header. *** If and only if the read is consistent and the header is different from ** pWal->hdr, then pWal->hdr is updated to the content of the new header ** and *pChanged is set to 1. *** If the checksum cannot be verified return non-zero. If the header ** is read successfully and the checksum verified, return zero.
66575. Calculate the phrase frequency (symbol "f(qi,D)" in the documentation) ** for each phrase in the query for the current row.

66576. First byte of the Cell
66577. ** Delete all entries in the %_segments table associated with the segment ** opened with seg-reader pSeg. This function does not affect the contents ** of the %_segdir table.
66578. ** Assuming mem5.zPool is divided up into an array of Mem5Link ** structures, return a pointer to the idx-th such link.
66579. ** For a compound SELECT statement, make sure p->pPrior->pNext==p for ** all elements in the list. And make sure list length does not exceed **
SQLITE_LIMIT_COMPOUND_SELECT.
66580. Initialize the output buffer
66581. FROM clause pLvl reads data from
66582. For looping over existing file IDs
66583. Disable the pCache->nPage validity check
66584. ** 2001 September 15 *** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** *** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** Main file for the SQLite library. The routines in this file **
implement the programmer interface to the library. Routines in ** other files are for internal use by SQLite and should not be ** accessed by users of the library.
66585. ** Rtree virtual table module xBestIndex method. There are three ** table scan strategies to choose from (in order from most to ** least desirable): *** *** idxNum
idxStr Strategy ** ----- ** 1 Unused Direct lookup by rowid. ** 2 See below R-tree query or full-table scan. ** -----
----- ** If strategy 1 is used, then idxStr is not meaningful. If strategy ** 2 is used, idxStr is formatted to contain 2 bytes for each **
constraint used. The first two bytes of idxStr correspond to ** the constraint in sqlite3_index_info.aConstraintUsage[] with ** (argvIndex==1) etc. *** *** The first
of each pair of bytes in idxStr identifies the constraint ** operator as follows: *** *** Operator Byte Value ** ----- ** = 0x41 ('A') ** <= 0x42 ('B') **
< 0x43 ('C') ** >= 0x44 ('D') ** > 0x45 ('E') ** MATCH 0x46 ('F') ** ----- ** The second of each pair of bytes identifies the coordinate column
** to which the constraint applies. The leftmost coordinate column ** is 'a', the second from the left 'b' etc.
66586. Operator(s) to scan for
66587. !defined(SQLITE_HWTIME_H)
66588. Unsigned integer types. These are already defined in the sqliteInt.h, ** but the definitions need to be repeated for separate compilation.
66589. Many of the flag-pragmas modify the code generated by the SQL ** compiler (eg. count_changes). So add an opcode to expire all ** compiled SQL statements
after modifying a pragma value.
66590. ***** End of wal.c *****
66591. Length of z in bytes
66592. Segment id
66593. Number of entries in argv[]
66594. non-ASCII codepoint read from input
66595. ** Constructor for a new stmt_cursor object.
66596. ** Locate or create an AutoincInfo structure associated with table pTab ** which is in database iDb. Return the register number for the register ** that holds the
maximum rowid. Return zero if pTab is not an AUTOINCREMENT ** table. (Also return zero when doing a VACUUM since we do not want to ** update the
AUTOINCREMENT counters during a VACUUM.) *** There is at most one AutoincInfo structure per table even if the ** same table is autoincremented
multiple times due to inserts within ** triggers. A new AutoincInfo structure is created if this is the ** first use of table pTab. On 2nd and subsequent uses, the
original ** AutoincInfo structure is used. *** Three memory locations are allocated: *** *** (1) Register to hold the name of the pTab table. ** (2) Register to
hold the maximum ROWID of pTab. ** (3) Register to hold the rowid in sqlite_sequence of pTab *** *** The 2nd register is the one that is returned. That is all the
*** insert routine needs to know about.
66597. ** Destroy a tokenizer allocated by unicodeCreate().
66598. Releasing a reserved lock
66599. ***** End of resolve.c *****
66600. ** Advance the cursor to the next row in the table.
66601. The top of the parser's stack
66602. Make sure the allocated memory does not assume that it is set to zero ** or retains a value from a previous allocation
66603. 197
66604. defer MT decisions to system malloc
66605. Appended to wal file

***** \$Id: icu.c,v 1.7 2007/12/13 21:54:11 drh Exp \$ *** This file

implements an integration between the ICU library ("International Components for Unicode", an open-source library for handling unicode data) and SQLite. The integration uses ICU to provide the following to SQLite: An implementation of the SQL regexp() function (and hence REGEXP operator) using the ICU uregex_XX() APIs. Implementations of the SQL scalar upper() and lower() functions for case mapping. Integration of ICU and SQLite collation sequences. An implementation of the LIKE operator that uses ICU to provide case-independent matching.

66780. Add the page to the PGroup LRU list.

66781. No digits

66782. Remove entries from the hash table that point to WAL slots greater than pWal->hdr.mxFrame. This function is called whenever pWal->hdr.mxFrame is decreased due to a rollback or savepoint. At most only the hash table containing pWal->hdr.mxFrame needs to be updated. Any later hash tables will be automatically cleared when pWal->hdr.mxFrame advances to the point where those hash tables are actually needed.

66783. Write search results here

66784. If the update-hook or pre-update-hook will be invoked, set zDb to the name of the db to pass as to it. Also set local pTab to a copy of p4.pTab. Finally, if p5 is true, indicating that this cursor was last moved with OP_Next or OP_Prev, not Seek or NotFound, set VdbeCursor.moveToTarget to the current rowid.

66785. Return true if the page is already in the journal file.

66786. FTS5_STRING node this phrase is part of

66787. Length of string argv[2]

66788. All code in this file should access the global structure above via the alias "pcache1". This ensures that the WSD emulation is used when compiling for systems that do not support real WSD.

66789. If any data has been written (but not committed) to the log file, this function moves the write-pointer back to the start of the transaction. Additionally, the callback function is invoked for each frame written to the WAL since the start of the transaction. If the callback returns other than SQLITE_OK, it is not invoked again and the error code is returned to the caller. Otherwise, if the callback function does not return an error, this function returns SQLITE_OK.

66790. We only need to generate a select expression if there is a limit/offset term to enforce.

66791. Free the pBt->pTmpSpace allocation

66792. EQ seeks only - no range seeks

66793. Sorter cursor

66794. The methods of the json_tree virtual table.

66795. Lower bound on the range. ex: "x>123" Might be NULL

66796. Length of the name

66797. Where clause to locate temp triggers

66798. The following routines are implementations of the MemPage.xCellSize method. Compute the total number of bytes that a Cell needs in the cell data area of the btree-page. The return number includes the cell data header and the local payload, but not any overflow page or the space used by the cell pointer. cellSizePtrNoPayload() => table internal nodes cellSizePtr() => all index nodes & table leaf nodes

66799. Set the variable isMemdb to true for an in-memory database, or false for a file-based database.

66800. ON clause terms may not be used with an index on left table of a LEFT JOIN. Ticket #3015

66801. file handle

66802. Checksum used for sanity checking

66803. Used to iterate through attached tables

66804. See comment below

66805. A table in the database is locked

66806. Database filename (UTF-8)

66807. 0x1a

66808. pTask->list.aMemory can only be non-zero if it was handed memory from the main thread. That only occurs SQLITE_MAX_WORKER_THREADS>0

66809. Insert a record into the %_docszie table. Specifically, do: INSERT OR REPLACE INTO %_docszie(id, sz) VALUES(iRowid, pBuf); If there is no %_docszie table (as happens if the columnsize=0 option is specified when the FTS5 table is created), this function is a no-op.

66810. Check to ensure that the cursor is valid. Restore the cursor if need be. Return any I/O error from the restore operation.

66811. The current column index in pp2

66812. Flags passed through to the VFS

66813. Used by: table_info

66814. Length of the zJson string in bytes

66815. An rbu VFS is implemented using an instance of this structure.

66816. Decoded coordinates

66817. **comment:** The VdbeCoverage macros are used to set a coverage testing point for VDBE branch instructions. The coverage testing points are line numbers in the sqlite3.c source file. VDBE branch coverage testing only works with an amalgamation build. That's ok since a VDBE branch coverage build designed for testing the test suite only. No application should ever ship with VDBE branch coverage measuring turned on. VdbeCoverage(v) // Mark the previously coded instruction as a branch *** VdbeCoverageIf(v, conditional) // Mark previous if conditional true *** VdbeCoverageAlwaysTaken(v) // Previous branch is always taken *** VdbeCoverageNeverTaken(v) // Previous branch is never taken *** Every VDBE branch operation must be tagged with one of the macros above. If not, then when "make test" is run with -DSQLITE_VDBE_COVERAGE and -DSQLITE_DEBUG then an ALWAYS() will fail in the vdbeTakeBranch() routine in vdbe.c, alerting the developer to the missed tag.

label: test

66916. 265

66917. ** Set *pnMax to the largest segment level in the database for the index ** iIndex. *** Segment levels are stored in the 'level' column of the %_segdir table. ** ** Return SQLITE_OK if successful, or an SQLite error code if not.

66918. Unmap the database file. It is possible that external processes ** may have truncated the database file and then extended it back ** to its original size while this process was not holding a lock. ** In this case there may exist a Pager.pMap mapping that appears ** to be the right size but is not actually valid. Avoid this ** possibility by unmapping the db here.

66919. The output line number is small enough that we are still in the ** main program.

66920. ** sqlite3_test_control(SQLITE_TESTCTRL_ALWAYS, int X) *** This action provides a run-time test to see how the ALWAYS and ** NEVER macros were defined at compile-time. *** The return value is ALWAYS(X). *** The recommended test is X==2. If the return value is 2, that means ** ALWAYS() and NEVER() are both no-op pass-through macros, which is the ** default setting. If the return value is 1, then ALWAYS() is either ** hard-coded to true or else it asserts if its argument is false. ** The first behavior (hard-coded to true) is the case if ** SQLITE_TESTCTRL_ASSERT shows that assert() is disabled and the second ** behavior (assert if the argument to ALWAYS() is false) is the case if ** SQLITE_TESTCTRL_ASSERT shows that assert() is enabled. *** The run-time test procedure might look something like this: *** ** if(sqlite3_test_control(SQLITE_TESTCTRL_ALWAYS, 2)==2){ ** // ALWAYS() and NEVER() are no-op pass-through macros ** }else if(sqlite3_test_control(SQLITE_TESTCTRL_ASSERT, 1)){ ** // ALWAYS(x) asserts that x is true. NEVER(x) asserts x is false. ** }else{ ** // ALWAYS(x) is a constant 1. NEVER(x) is a constant 0. ** }

66921. Root BTree page for this table

66922. Offset to the start of the cell pointer array

66923. SELECT statement to encode

66924. ** The input pointer currently points to the first byte of the first field ** of a record consisting of nCol columns. This function ensures the entire ** record is buffered. It does not move the input pointer. *** If successful, SQLITE_OK is returned and *pnByte is set to the size of ** the record in bytes. Otherwise, an SQLite error code is returned. The ** final value of *pnByte is undefined in this case.

66925. True if ok to populate

66926. The unix errno from last I/O error

66927. ** x BETWEEN y AND z *** This is equivalent to ** ** x>=y AND x<=z ** ** X is stored in pExpr->pLeft. ** Y is stored in pExpr->pList->a[0].pExpr. ** Z is stored in pExpr->pList->a[1].pExpr.

66928. The column that is wanted

66929. sqlite3_test_control(SQLITE_TESTCTRL_ISKEYWORD, const char *zWord) *** If zWord is a keyword recognized by the parser, then return the ** number of keywords. Or if zWord is not a keyword, return 0. *** This test feature is only available in the amalgamation since ** the SQLITE_N_KEYWORD macro is not defined in this file if SQLite ** is built using separate source files.

66930. Number of registers to allocate

66931. **comment:** Initialized only to suppress erroneous warning from Clang
label: code-design

66932. ** Parse a timezone extension on the end of a date-time. ** The extension is of the form: ** ** (+-)HH:MM ** ** Or the "zulu" notation: ** ** Z ** ** If the parse is successful, write the number of minutes ** of change in p->tz and return 0. If a parser error occurs, ** return non-zero. *** A missing specifier is not considered an error.

66933. Output values used by 'row' and 'col' tables

66934. Rowid changed in a normal table

66935. **comment:** Cursor for the index, if pIdx!=0. Unused otherwise
label: code-design

66936. **comment:** Case 4: A scan using an index. *** The WHERE clause may contain zero or more equality ** terms ("==" or "IN" operators) that refer to the N ** left-most columns of the index. It may also contain ** inequality constraints (>, <, >= or <=) on the indexed ** column that immediately follows the N equalities. Only ** the right-most column can be an inequality - the rest must ** use the "==" and "IN" operators. For example, if the ** index is on (x,y,z), then the following clauses are all ** optimized: *** x=5 ** x=5 AND y=10 ** x=5 AND y<10 ** x=5 AND y>5 AND y<10 ** x=5 AND y=5 AND z<=10 *** The z<10 term of the following cannot be used, only ** the x=5 term: *** x=5 AND z<10 ** ** N may be zero if there are inequality constraints. ** If there are no inequality constraints, then N is at ** least one. *** This case is also used when there are no WHERE clause ** constraints but an index is selected anyway, in order ** to force the output order to conform to an ORDER BY.
label: code-design

66937. Encoding for the data

66938. If this is an INSERT or UPDATE, read the new.* record.

66939. OP_Found will use a composite key

66940. Iterator error code

66941. The various pragma types

66942. 0xff means setting unknown

66943. If opening the main database, set ENC(db).

66944. Special handling for a compound-select that originates as a VALUES clause.

66945. ** Create an Fts5Iter that iterates through the doclist provided ** as the second argument.

66946. ** Called by the parser to compile an ATTACH statement. *** ATTACH p AS pdbname KEY pKey

66947. ** Return the file handle for the journal file (if it exists). ** This will be either the rollback journal or the WAL file.

66948. The base for radix conversion

66949. 157

66950. same as TK_EQ, synopsis: IF r[P3]==r[P1]

66951. ** 2009 January 28 *** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **

***** This file contains the implementation of the sqlite3_backup_XXX()

** API functions and the related features.

66952. P1==1 for end-of-loop

66953. Confirm that aiMap[] contains nVector integer values between 0 and ** nVector-1.

66954. Append a comma separator to the output buffer, if the previous ** character is not '[' or ']'.
66955. 0x1b
66956. List of indexed columns
66957. ALWAYS() justification: eOp is an equality operator due to the ** j<pLoop->u.btree.nEq constraint above. Any equality other ** than WO_IN is captured by the previous "if". So this one ** always has to be WO_IN.
66958. end Loop over all index columns
66959. ** Get a page from the pager. Initialize the MemPage.pBt and ** MemPage.aData elements if needed. See also: btreeGetUnusedPage(). *** If the PAGER_GET_NOCONTENT flag is set, it means that we do not care ** about the content of the page at this time. So do not go to the disk ** to fetch the content. Just fill in the content with zeros for now. ** If in the future we call sqlite3PagerWrite() on this page, that ** means we have started to be concerned about content and the disk ** read should occur at that point.
66960. ** Available fault injectors. Should be numbered beginning with 0.
66961. Size of record header in bytes
66962. ORDERBY+LIMIT on the inner loop
66963. Name of variables
66964. .n =
66965. 17
66966. Logarithm of table size
66967. True if trailing zeros should be removed
66968. The wal-index is divided into pages of WALINDEX_PGSZ bytes each.
66969. Number of XOR operations done
66970. The table does not exist.
66971. Used when p4type is P4_KEYINFO
66972. Assuming no error has occurred, run a "restart" checkpoint with the ** sqlite3rbu.eStage variable set to CAPTURE. This turns on the following ** special behaviour in the rru VFS: *** If the exclusive shm WRITER or READ0 lock cannot be obtained, ** the checkpoint fails with SQLITE_BUSY (normally SQLite would ** proceed with running a passive checkpoint instead of failing). *** Attempts to read from the *-wal file or write to the database file ** do not perform any IO. Instead, the frame/page combinations that ** would be read/written are recorded in the sqlite3rbu.aFrame[] ** array. *** Calls to xShmLock(UNLOCK) to release the exclusive shm WRITER, ** READ0 and CHECKPOINT locks taken as part of the checkpoint are ** no-ops. These locks will not be released until the connection ** is closed. *** Attempting to xSync() the database file causes an SQLITE_INTERNAL ** error. *** As a result, unless an error (i.e. OOM or SQLITE_BUSY) occurs, the ** checkpoint below fails with SQLITE_INTERNAL, and leaves the aFrame[] ** array populated with a set of (frame -> page) mappings. Because the ** WRITER, CHECKPOINT and READ0 locks are still held, it is safe to copy ** data from the wal file into the database file according to the ** contents of aFrame[].
66973. Set to zero if any values are modified
66974. Opcode: ReadCookie P1 P2 P3 * * * * * Read cookie number P3 from database P1 and write it into register P2. ** P3==1 is the schema version. P3==2 is the database format. ** P3==3 is the recommended pager cache size, and so forth. P1==0 is ** the main database file and P1==1 is the database file used to store ** temporary tables. *** There must be a read-lock on the database (either a transaction ** must be started or there must be an open cursor) before ** executing this instruction.
66975. ** If the most recently coded instruction is a constant range constraint ** (a string literal) that originated from the LIKE optimization, then ** set P3 and P5 on the OP_String opcode so that the string will be cast ** to a BLOB at appropriate times. *** The LIKE optimization tries to evaluate "x LIKE 'abc%'" as a range ** expression: "x>='ABC' AND x<'abd'". But this requires that the range ** scan loop run twice, once for strings and a second time for BLOBS. ** The OP_String opcodes on the second pass convert the upper and lower ** bound string constants to blobs. This routine makes the necessary changes ** to the OP_String opcodes for that to happen. ** ** Except, of course, if SQLITE_LIKE_DOESNT_MATCH_BLOBS is defined, then ** only the one pass through the string space is required, so this routine ** becomes a no-op.
66976. Cursor used for index scans (if any)
66977. Size of apPhrase array
66978. The above might be initialized to non-zero. The following need to always ** initially be zero, however.
66979. ** Append a rowid and position-list size field to the writers output.
66980. Test if fcntl() is supported and use POSIX style locks. ** Otherwise fall back to the named semaphore method.
66981. 840
66982. Register holding the offset counter
66983. **comment:** If [0] is unused then [1] is also unused. So we can ** always safely abort as soon as the first unused slot is found
 label: code-design
66984. Next free argvIndex value
66985. Full-text table
66986. selectnowith
66987. Connection handle
66988. The 1-byte case. Overwhelmingly the most common.
66989. Pointer to buffer containing changeset A
66990. ONEPASS defaults to OFF
66991. Encoding of z. 0 for BLOBS
66992. defined(SQLITE_USE_MALLOC_H)
66993. True if db currently has pBt locked
66994. **comment:** LIMIT expression. NULL means not used.
 label: code-design
66995. ** Read the next nByte bytes of data from the PMA p. ** If successful, set *ppOut to point to a buffer containing the data ** and return SQLITE_OK. Otherwise, if an error occurs, return an SQLite ** error code. *** The buffer returned in *ppOut is only valid until the ** next call to this function.
66996. ** The argument to this macro is a file descriptor (type sqlite3_file*). ** Return 0 if it is not open, or non-zero (but not 1) if it is. *** This is so that expressions can be written as: *** if(isOpen(pPager->jfd)){ ... } instead of *** if(pPager->jfd->pMethods){ ... }
66997. Mark the expression is being from the ON or USING clause of a join ** so that the sqlite3ExprCodeTarget() routine will not attempt to move ** it into the Parse.pConstExpr list. We should use a new bit for this, ** for clarity, but we are out of bits in the Expr.flags field so we ** have to reuse the EP_FromJoin bit. Bummer.
66998. The current schema
66999. ** Memory cell pMem contains the context of an aggregate function. ** This routine calls the finalize method for that function. The ** result of the aggregate is stored back into pMem. *** Return SQLITE_ERROR if the finalizer reports an error. SQLITE_OK ** otherwise.
67000. Figure out if we have any triggers and if the table being ** inserted into is a view
67001. Integer value if p4type==P4_INT32
67002. Address of the A>B subroutine
67003. Flags allowed as part of the 4th argument to SegmentReaderIterate()
67004. SQLITE_IOERR
67005. LIKE opt constraints
67006. If the column value is a string, we need a persistent value, not ** a MEM_Ephem value. This branch is a fast short-cut that is equivalent ** to calling sqlite3VdbeSerialGet() and sqlite3VdbeDeepHemeralize().
67007. Release/Acquire the system-level lock
67008. An unrecognized directive. Return an error message.
67009. Function to possibly overload

67010. If pFree is not NULL, it points to the pSpace buffer used ** by a previous call to balance_nonroot(). Its contents are ** now stored either on real database pages or within the ** new pSpace buffer, so it may be safely freed here.

67011. A negative nCol is a special marker meaning that we are currently ** trying to compute the column names. If we enter this routine with ** a negative nCol, it means two or more views form a loop, like this: ** ** CREATE VIEW one AS SELECT * FROM two; ** CREATE VIEW two AS SELECT * FROM one; ** ** Actually, the error above is now caught prior to reaching this point. ** But the following test is still important as it does come up ** in the following: ** ** CREATE TABLE main.ex1(a); ** CREATE TEMP VIEW ex1 AS SELECT a FROM ex1; ** SELECT * FROM temp.ex1;

67012. Segment id to load from

67013. If the target table column is an "INTEGER PRIMARY KEY", add ** "PRIMARY KEY" to the imposter table column declaration.

67014. same as TK_GE, synopsis: IF r[P3]>=r[P1]

67015. SQLITE_OS_WIN_H

67016. **comment:** The P4 parameter is not used
label: code-design

67017. ** Append a DELETE change to the buffer passed as the first argument. Use ** the changeset format if argument bPatchset is zero, or the patchset ** format otherwise.

67018. Remove the FK from the fkeyHash hash table.

67019. The first in an array of registers (see above)

67020. ** Compute the parentage of all nodes in a completed parse.

67021. ***** Begin file random.c *****

67022. 116

67023. ** Rtree virtual table module xColumn method.

67024. Since the names of named mutexes, semaphores, file mappings etc are ** case-sensitive, take advantage of that by uppercasing the mutex name ** and using that as the shared filemapping name.

67025. Name of the table

67026. 231

67027. Fill the index with data and reparse the schema. Code an OP_Expire ** to invalidate all pre-compiled statements.

67028. REGEXP

67029. Value to return in *pnEntry

67030. The spec says there are three possible values for flags. But only ** two of them are actually used

67031. Copy the b-tree node content from page pFrom to page pTo.

67032. The parser action.

67033. Sub-vdbe for trigger program

67034. sqlite3_randomness()

67035. #include "sqlite3.h"

67036. Number of bytes in current term

67037. Convert indexed expr to column

67038. lock the RESERVED byte

67039. A copy of pExpr is used instead of the original, as pExpr contains ** tokens that point to volatile memory. The 'span' of the expression ** is required by pragma table_info.

67040. ** pRoot is the root of an incremental merge-tree with depth nDepth (according ** to vdbeSorterTreeDepth()). pLeaf is the iSeq'th leaf to be added to the ** tree, counting from zero. This function adds pLeaf to the tree. ** ** If successful, SQLITE_OK is returned. If an error occurs, an SQLite error ** code is returned and pLeaf is freed.

67041. SQLITE_INTERRUPT

67042. ** If a ReadFile() or WriteFile() error occurs, invoke this routine ** to see if it should be retried. Return TRUE to retry. Return FALSE ** to give up with an error.

67043. There is no reason any cursor should have an outstanding reference ** to an overflow page belonging to a cell that is being deleted/updated. ** So if there exists more than one reference to this page, then it ** must not really be an overflow page and the database must be corrupt. ** It is helpful to detect this before calling freePage2(), as ** freePage2() may zero the page contents if secure-delete mode is ** enabled. If this 'overflow' page happens to be a page that the ** caller is iterating through or using in some other way, this ** can be problematic.

67044. ** If the following function pointer is not NULL and if ** SQLITE_ENABLE_IOTRACE is enabled, then messages describing ** I/O active are written using this function. These messages ** are intended for debugging activity only.

67045. Number of loaded extensions

67046. Cursor that holds the new sorter

67047. Case-sensitive LIKE-type function

67048. String, possibly obtained from sqlite3_malloc

67049. Current checkout, including internal fragmentation

67050. Rowid that P1 current points to

67051. Make the IdChar function accessible from ctime.c

67052. varintRecordCompareInt() and varintRecordCompareString() both assume ** that the size-of-header varint that occurs at the start of each record ** fits in a single byte (i.e. is 127 or less). varintRecordCompareInt() ** also assumes that it is safe to overread a buffer by at least the ** maximum possible legal header size plus 8 bytes. Because there is ** guaranteed to be at least 74 (but not 136) bytes of padding following each ** buffer passed to varintRecordCompareInt() this makes it convenient to ** limit the size of the header to 64 bytes in cases where the first field ** is an integer. ** ** The easiest way to enforce this limit is to consider only records with ** 13 fields or less. If the first field is an integer, the maximum legal ** header size is (12*5 + 1 + 1) bytes.

67053. ** Destructor for a stmt_cursor.

67054. ** Return the size of an outstanding allocation, in bytes. The ** size returned omits the 8-byte header overhead. This only ** works for chunks that are currently checked out.

67055. IN/OUT: Point to read varint from

67056. Next session object on same db.

67057. True if a plan with no prereqs seen

67058. Figure out how many memory cells we will need then allocate them.

67059. ** We say the WhereLoop is "one-row" if it generates no more than one ** row of output. A WhereLoop is one-row if all of the following are true: ** (a) All index columns match with WHERE_COLUMN_EQ. ** (b) The index is unique ** Any WhereLoop with an WHERE_COLUMN_EQ constraint on the rowid is one-row. ** Every one-row WhereLoop will have the WHERE_ONEROW bit set in wsFlags. ** ** We say the WhereLoop is "order-distinct" if the set of columns from ** that WhereLoop that are in the ORDER BY clause are different for every ** row of the WhereLoop. Every one-row WhereLoop is automatically ** order-distinct. A WhereLoop that has no columns in the ORDER BY clause ** is not order-distinct. To be order-distinct is not quite the same as being ** UNIQUE since a UNIQUE column or index can have multiple rows that ** are NULL and NULL values are equivalent for the purpose of order-distinct. ** To be order-distinct, the columns must be UNIQUE and NOT NULL. ** ** The rowid for a table is always UNIQUE and NOT NULL so whenever the ** rowid appears in the ORDER BY clause, the corresponding WhereLoop is ** automatically order-distinct.

67060. The Current table

67061. <tbl> MATCH ?

67062. Bytes consumed per cell

67063. Column constrained. -1 for ROWID

67064. **comment:** COVERAGE: The (pVal->z==0) branch is never true using current versions ** of SQLite. If a malloc fails in an sqlite3_value_xxx() function, either ** the (pVal->z) variable remains as it was or the type of the value is ** set to SQLITE_NULL.
label: code-design

67065. Number of a[] slots allocated

67066. ** The methods above are in versions 1 and 2 of the sqlite_vfs object. ** Those below are for version 3 and greater.

67067. ** Return the number of bytes currently allocated at address p.

67068. ** This object holds a record which has been parsed out into individual ** fields, for the purposes of doing a comparison. ** ** A record is an object that contains one or more fields of data. ** Records are used to store the content of a table row and to store ** the key of an index. A blob encoding of a record is created by **

the OP_MakeRecord opcode of the VDBE and is disassembled by the ** OP_Column opcode. *** An instance of this object serves as a "key" for doing a search on ** an index b+tree. The goal of the search is to find the entry that ** is closed to the key described by this object. This object might hold ** just a prefix of the key. The number of fields is given by ** pKeyInfo->nField. *** The r1 and r2 fields are the values to return if this key is less than ** or greater than a key in the btree, respectively. These are normally ** -1 and +1 respectively, but might be inverted to +1 and -1 if the b-tree ** is in DESC order. *** The key comparison functions actually return default_rc when they find ** an equals comparison. default_rc can be -1, 0, or +1. If there are ** multiple entries in the b-tree with the same key (when only looking ** at the first pKeyInfo->nFields,) then default_rc can be set to -1 to ** cause the search to find the last match, or +1 to cause the search to ** find the first match. *** The key comparison functions will set eqSeen to true if they ever ** get equal results when comparing this structure to a b-tree record. ** When default_rc!=0, the search might end up on the record immediately ** before the first match or immediately after the last match. The ** eqSeen field will indicate whether or not an exact match exists in the ** b-tree.

67069. The following table contains information about every rule that ** is used during the reduce.

67070. IN: Elements in array *paLeft

67071. Set up the required files for pIncr. A multi-threaded IncrMerge object ** requires two temp files to itself, whereas a single-threaded object ** only requires a region of pTask->file2.

67072. If an error occurs during a ROLLBACK, we can no longer trust the pager ** cache. So call pager_error() on the way out to make any error persistent.

67073. Used when p4type is P4_MEMORY

67074. An SQLITE_MISUSE error occurred

67075. 1 -> main journal. 0 -> sub-journal.

67076. OUT: Final number of checkpointed frames

67077. Number of bytes in key

67078. Address of subroutine to manifest a subquery

67079. Length of the source file

67080. Disable lookaside memory allocation

67081. Generate a select expression tree to enforce the limit/offset ** term for the DELETE or UPDATE statement. For example: ** DELETE FROM table_a WHERE col1=1 ORDER BY col2 LIMIT 1 OFFSET 1 ** becomes: ** DELETE FROM table_a WHERE rowid IN (** SELECT rowid FROM table_a WHERE col1=1 ORDER BY col2 LIMIT 1 OFFSET 1 **);

67082. ** Generate code for a boolean expression such that a jump is made ** to the label "dest" if the expression is true but execution ** continues straight thru if the expression is false. *** If the expression evaluates to NULL (neither true nor false), then ** take the jump if the jumpIfNull flag is SQLITE_JUMPNULL. ** This code depends on the fact that certain token values (ex: TK_EQ) ** are the same as opcode values (ex: OP_Eq) that implement the corresponding ** operation. Special comments in vdbe.c and the mkopcodeh.awk script in ** the make process cause these values to align. Assert(s) in the code ** below verify that the numbers are aligned correctly.

67083. Reserved space for locks

67084. MEM cell holding key for the record

67085. ** Unless it is NULL, the argument must be an UnpackedRecord object returned ** by an earlier call to sqlite3Stat4ProbeSetValue(). This call deletes ** the object.

67086. If the database supports auto-vacuum, write an entry in the pointer-map ** to indicate that the page is free.

67087. EXISTS => nothing

67088. OUT: Block number in next layer down

67089. on_opt ::=

67090. ** The sqlite3_mutex_held() and sqlite3_mutex_notheld() routine are ** intended for use inside assert() statements.

67091. Flags for the fsync

67093. Index of iDelete cell in pLeaf

67094. ***** Include btree.h in the middle of sqliteInt.h *****

67095. Position just read from pList

67096. Beginning of the header. 0 most pages. 100 page 1

67097. Property flags associated with various pragma.

67098. Matchinfo format string

67099. Translate the schema name in zDb into a pointer to the corresponding ** schema. If not found, pSchema will remain NULL and nothing will match ** resulting in an appropriate error message toward the end of this routine

67100. The "wsdAutoext" macro will resolve to the autoextension ** state vector. If writable static data is unsupported on the target, ** we have to locate the state vector at run-time. In the more common ** case where writable static data is supported, wsdStat can refer directly ** to the "sqlite3Autoext" state vector declared above.

67101. ** The file-handle passed as the only argument is open on a journal file. ** Return true if this "journal file" is currently stored in heap memory, ** or false otherwise.

67102. ** The json_parse(JSON) function returns a string which describes ** a parse of the JSON provided. Or it returns NULL if JSON is not ** well-formed.

67103. True if rbu_count exists

67104. **comment:** Use register aRegIdx[i] for index i. 0 for unused

label: code-design

67105. eidlist ::= eidlist COMMA nm collate sortorder

67106. If the current number of pages in the file is greater than the ** configured maximum pager number, increase the allowed limit so ** that the file can be read.

67107. 0x4

67108. Size of doclist in current entry

67109. ** Populate the buffer pInfo->aMatchinfo[] with an array of integers to ** be returned by the matchinfo() function. Argument zArg contains the ** format string passed as the second argument to matchinfo (or the ** default value "pcx" if no second argument was specified). The format ** string has already been validated and the pInfo->aMatchinfo[] array ** is guaranteed to be large enough for the output. *** If bGlobal is true, then populate all fields of the matchinfo() output. ** If it is false, then assume that those fields that do not change between ** rows (i.e. FTS3_MATCHINFO_NPHRASE, NCOL, NDOC, AVGLENGTH and part of HITS) ** have already been populated. *** Return SQLITE_OK if successful, or an SQLite error code if an error ** occurs. If a value other than SQLITE_OK is returned, the state the ** pInfo->aMatchinfo[] buffer is left in is undefined.

67110. ** Initialize an array of N Mem element.

67111. ** When this function is called, *ppRec points to the start of a record ** that contains nCol values. This function advances the pointer *ppRec ** until it points to the byte immediately following that record.

67112. IMPLEMENTATION-OF: R-63124-39300 The sqlite3_sourceid() function returns a ** pointer to a string constant whose value is the same as the ** SQLITE_SOURCE_ID C preprocessor macro.

67113. nearphrases ::= nearphrases phrase

67114. Largest payload of any cell on this page

67115. A frame is only valid if the page number is greater than zero.

67116. select

67117. Callback for SELECTs

67118. No-op versions of the explainXXX() functions and macros.

67119. ** Make sure virtual table pTab is contained in the pParse->apVirtualLock[] ** array so that an OP_VBegin will get generated for it. Add pTab to the ** array if it is missing. If pTab is already in the array, this routine ** is a no-op.

67120. Opcode: NoConflict P1 P2 P3 P4 *** Synopsis: key=r[P3@P4] *** If P4==0 then register P3 holds a blob constructed by MakeRecord. If ** P4>0 then register P3 is the first of P4 registers that form an unpacked ** record. *** Cursor P1 is on an index btree. If the record identified by P3 and P4 ** contains any NULL value, jump immediately to P2. If all terms of the ** record are not-NULL then a check is done to determine if any row in the ** P1 index btree has a matching key prefix. If there are no matches, jump ** immediately to P2. If there is a match, fall through and leave the P1 ** cursor pointing to the matching row. *** This opcode is similar to OP_NotFound with the exceptions that the ** branch is always taken if any part of the search key input is NULL. *** This operation leaves the cursor in a state where it cannot be ** advanced in either direction. In other words, the Next and Prev ** opcodes do not work after this operation. *** See also: NotFound, Found, NotExists

67121. ROWID value for this entry

67122. If the above was successful, each component iterators now points ** to the first entry in its segment. In this case initialize the ** aFirst[] array. Or, if an error has occurred, free the iterator ** object and set the output variable to NULL.

67123. Functions used to configure a Pager object.

67124. ** Return a 32-bit integer value extracted from a string. If the ** string is not an integer, just return 0.

67125. If we succeeded in making the shared memory handle, map it.

67126. If there is more header available for parsing in the record, try ** to extract additional fields up through the p2+1-th field

67127. Callback function to invoke for phrases

67128. ** Compile the UTF-16 encoded SQL statement zSql into a statement handle.

67129. 0x19

67130. SQL used to determine first block

67131. Number of args

67132. ** Set a flag in the vdbe to update the change counter when it is finalised ** or reset.

67133. One of several kinds of errors

67134. ** Return the number of rows inserted. If this routine is ** generating code because of a call to sqlite3NestedParse(), do not ** invoke the callback function.

67135. The following was already done in fts5WriteInit():

67136. OUT: Hash value

67137. Number of pages on the overflow chain

67138. Shifts left before out of the error

67139. Resolve names in all CHECK constraint expressions.

67140. TRIGGER => ID

67141. ***** Include os_common.h in the middle of os_win.c *****

67142. **comment:** Cannot be both CLEAN and DIRTY
label: code-design

67143. ** This function is called to edit the position list associated with ** the phrase object passed as the fifth argument according to a NEAR ** condition. For example: *** abc NEAR/5 "def ghi" *** Parameter nNear is passed the NEAR distance of the expression (5 in ** the example above). When this function is called, *paPoslist points to ** the position list, and *pnToken is the number of phrase tokens in, the ** phrase on the other side of the NEAR operator to pPhrase. For example, ** if pPhrase refers to the "def ghi" phrase, then *paPoslist points to ** the position list associated with phrase "abc". *** All positions in the pPhrase position list that are not sufficiently ** close to a position in the *paPoslist position list are removed. If this ** leaves 0 positions, zero is returned. Otherwise, non-zero. *** Before returning, *paPoslist is set to point to the position lsit ** associated with pPhrase. And *pnToken is set to the number of tokens in ** pPhrase.

67144. segdir.start_block

67145. Structure of specific index

67146. ** Install the pre-update hooks on the session object passed as the only ** argument.

67147. Size of argv array

67148. Return the total number of outstanding page references

67149. return if parameter is missing

67150. ** Delete a session object previously allocated using sqlite3session_create().

67151. Update the private copy of the header.

67152. ** An object of this type is created for each virtual table present in ** the database schema. *** If the database schema is shared, then there is one instance of this ** structure for each database connection (sqlite3*) that uses the shared ** schema. This is because each database connection requires its own unique ** instance of the sqlite3_vtab* handle used to access the virtual table ** implementation. sqlite3_vtab* handles can not be shared between ** database connections, even when the rest of the in-memory database ** schema is shared, as the implementation often stores the database ** connection handle passed to it via the xConnect() or xCreate() method ** during initialization internally. This database connection handle may ** then be used by the virtual table implementation to access real tables ** within the database. So that they appear as part of the callers ** transaction, these accesses need to be made via the same database ** connection as that used to execute SQL operations on the virtual table. *** All VTable objects that correspond to a single table in a shared ** database schema are initially stored in a linked-list pointed to by ** the Table.pVTable member variable of the corresponding Table object. ** When an sqlite3_prepare() operation is required to access the virtual ** table, it searches the list for the VTable that corresponds to the ** database connection doing the preparing so as to use the correct ** sqlite3_vtab* handle in the compiled query. *** When an in-memory Table object is deleted (for example when the ** schema is being reloaded for some reason), the VTable objects are not ** deleted and the sqlite3_vtab* handles are not xDisconnect()ed ** immediately. Instead, they are moved from the Table.pVTable list to ** another linked list headed by the sqlite3_pDisconnect member of the ** corresponding sqlite3 structure. They are then deleted/xDisconnected ** next time a statement is prepared using said sqlite3*. This is done ** to avoid deadlock issues involving multiple sqlite3.mutex mutexes. ** Refer to comments above function sqlite3VtabUnlockList() for an ** explanation as to why it is safe to add an entry to an sqlite3.pDisconnect ** list without holding the corresponding sqlite3.mutex mutex. *** The memory for objects of this type is always allocated by ** sqlite3DbMalloc(), using the connection handle stored in VTable.db as ** the first argument.

67153. Jump here if we hit the LIMIT

67154. ** Remove the cell with index iCell from node pNode.

67155. ** Initialize and deinitialize the operating system interface.

67156. Malloc'd master-journal file descriptor

67157. 226

67158. ***** The json_each virtual table*****

67159. Jump here to skip this query

67160. If work was actually accomplished...

67161. ** Set the busy handler function. *** The pager invokes the busy-handler if sqlite3OsLock() returns ** SQLITE_BUSY when trying to upgrade from no-lock to a SHARED lock, ** or when trying to upgrade from a RESERVED lock to an EXCLUSIVE ** lock. It does *not* invoke the busy handler when upgrading from ** SHARED to RESERVED, or when upgrading from SHARED to EXCLUSIVE ** (which occurs during hot-journal rollback). Summary: *** Transition | Invokes xBusyHandler ** ----- ** NO_LOCK -> SHARED_LOCK | Yes ** SHARED_LOCK -> RESERVED_LOCK | No ** SHARED_LOCK -> EXCLUSIVE_LOCK | No ** RESERVED_LOCK -> EXCLUSIVE_LOCK | Yes *** If the busy-handler callback returns non-zero, the lock is ** retried. If it returns zero, then the SQLITE_BUSY error is ** returned to the caller of the pager API function.

67162. At this point the client has a lock on an aReadMark[] slot holding ** a value equal to or smaller than pSnapshot->mxFrame, but pWal->hdr ** is populated with the wal-index header corresponding to the head ** of the wal file. Verify that pSnapshot is still valid before ** continuing. Reasons why pSnapshot might no longer be valid: *** (1) The WAL file has been reset since the snapshot was taken. ** In this case, the salt will have changed. *** (2) A checkpoint as been attempted that wrote frames past ** pSnapshot->mxFrame into the database file. Note that the ** checkpoint need not have completed for this to cause problems.

67163. Apply the requested affinity to all inputs

67164. The cursor used for this query

67165. Fall through into OP_Rewind

67166. The value to apply affinity to

67167. Term to search for

67168. !defined(SQLITE_OMIT_VIRTUALTABLE)

67169. This function is only called for rollback pagers in WRITER_DBMOD state.

67170. If the DISTINCT keyword was present on the SELECT statement ** and this row has been seen before, then do not make this row ** part of the result.

67171. Pointer to hash table to clear

67172. The VDBE cursor number used to access this table

67173. Generate code to evaluate all constraint terms using == or IN ** and store the values of those terms in an array of registers ** starting at regBase.

67174. Populate the new SessionTable object and link it into the list. ** The new object must be linked onto the end of the list, not ** simply added to the start of it in order to ensure that tables ** appear in the correct order when a changeset or patchset is ** eventually generated.

67175. Pointer to filter object

67176. The node to render

67177. Nr. of entries in aPgn[] and aIndex[]

67178. True to run in heap-memory mode
67179. RHS is null
67180. 0x03
67181. ** Write iAmt bytes of content into the WAL file beginning at iOffset. ** Do a sync when crossing the p->iSyncPoint boundary. ** ** In other words, if iSyncPoint is in between iOffset and iOffset+iAmt, ** first write the part before iSyncPoint, then sync, then write the ** rest.
67182. (300) defer_subclause_opt ::= defer_subclause (OPTIMIZED OUT)
67183. ** The default size of a disk sector
67184. Current ordered scan item
67185. Initialize a term iterator for each term in the phrase
67186. Available memory locations begin here
67187. Cost of running each loop
67188. ** This routine is used for testing and analysis only.
67189. If the PRIMARY KEY expression is NULL, then use OP_NewRowid ** to generate a unique primary key value.
67190. 9x
67191. **comment:** ** This function is called after invoking an sqlite3_value_XXX function on a ** column value (i.e. a value returned by evaluating an SQL expression in the ** select list of a SELECT statement) that may cause a malloc() failure. If ** malloc() has failed, the threads mallocFailed flag is cleared and the result ** code of statement pStmt set to SQLITE_NOMEM. ** ** Specifically, this is called from within: ** ** sqlite3_column_int() ** sqlite3_column_int64() ** sqlite3_column_text() ** sqlite3_column_text16() ** sqlite3_column_real() ** sqlite3_column_bytes() ** sqlite3_column_bytes16() ** sqlite3_column_blob()
label: code-design
67192. ** This routine does per-connection function registration. Most ** of the built-in functions above are part of the global function set. ** This routine only deals with those that are not global.
67193. **comment:** ** The following group of routines make deep copies of expressions, ** expression lists, ID lists, and select statements. The copies can ** be deleted (by being passed to their respective ...Delete() routines) ** without effecting the originals. ** ** The expression list, ID, and source lists return by sqlite3ExprListDup(), ** sqlite3IdListDup(), and sqlite3SrcListDup() can not be further expanded ** by subsequent calls to sqlite*ListAppend() routines. ** ** Any tables that the SrcList might point to are not duplicated. ** ** The flags parameter contains a combination of the EXPRDUP_XXX flags. ** If the EXPRDUP_REDUCE flag is set, then the structure returned is a ** truncated version of the usual Expr structure that will be stored as ** part of the in-memory representation of the database schema.

67213. 280
67214. Return true if index X is a UNIQUE index
67215. OOM will cause exit after sqlite3Select()
67216. Size of buffer zDoc in bytes
67217. If this was page 1, then restore the value of Pager.dbFileVers. ** Do this before any decoding.
67218. Exit the mutexes and free the backup context structure.
67219. Iterator object to initialize
67220. ***** Include pcache.h in the middle of sqliteInt.h *****
67221. Test all CHECK constraints
67222. Add sign
67223. When the new root page was allocated, page 1 was made writable in ** order either to increase the database filesize, or to decrement the ** freelist count. Hence, the sqlite3BtreeUpdateMeta() call cannot fail.
67224. Maximum bit index. Max iSize is 4,294,967,296.
67225. The %p conversion
67226. Try to match the ORDER BY expression against an expression ** in the result set. Return an 1-based index of the matching ** result-set entry.
67227. Opcode: IncrVacuum P1 P2 * * * * * Perform a single step of the incremental vacuum procedure on ** the P1 database. If the vacuum has finished, jump to instruction ** P2. Otherwise, fall through to the next instruction.
67228. Handle the common case of integer comparison here, as an ** optimization, to avoid a call to sqlite3MemCompare()
67229. Content of the node, as should be on disk
67230. Modify the sqlite_master table to use the new table name.
67231. Previous index in the loop
67232. IMP: R-49053-54554
67233. 105
67234. ** Free the phrase object passed as the second argument.
67235. Initialize the shared memory if we're supposed to
67236. Parse structure for main program (or NULL)
67237. Length of the string so far
67238. Enlarge pJson->zBuf so that it can hold at least N more bytes. ** Return zero on success. Return non-zero on an OOM error
67239. ** Check if another file-handle holds a RESERVED lock on an rbuVfs-file.
67240. A stat() call may fail for various reasons. If this happens, it is ** almost certain that an open() call on the same path will also fail. ** For this reason, if an error occurs in the stat() call here, it is ** ignored and -1 is returned. The caller will try to open a new file ** descriptor on the same path, fail, and return an error to SQLite. ** ** Even if a subsequent open() call does succeed, the consequences of ** not searching for a reusable file descriptor are not dire.
67241. Populate the output variable and return success.
67242. The page size
67243. Opcode: CreateTable P1 P2 * * * * * Synopsis: r[P2]=root iDb=P1 ** ** Allocate a new table in the main database file if P1==0 or in the ** auxiliary database file if P1==1 or in an attached database if ** P1>1. Write the root page number of the new table into ** register P2 ** ** The difference between a table and an index is this: A table must ** have a 4-byte integer key and can have arbitrary data. An index ** has an arbitrary key but no data. ** ** See also: CreateIndex
67244. True while initialization in progress
67245. ** If cursors, triggers, views and subqueries are all omitted from ** the build, then none of the following routines, except for ** sqlite3SelectDup(), can be called. sqlite3SelectDup() is sometimes ** called with a NULL argument.

67246. ** Return a simple checksum value based on the arguments.

67247. **comment:** ** CAPI3REF: Finalize A Changeset Iterator *** This function is used to finalize an iterator allocated with ** [sqlite3changeset_start()]. *** This function should only be called on iterators created using the ** [sqlite3changeset_start()] function. If an application calls this ** function with an iterator passed to a conflict-handler by ** [sqlite3changeset_apply()], [SQLITE_MISUSE] is immediately returned and the ** call has no effect. *** If an error was encountered within a call to an sqlite3changeset_xxx() ** function (for example an [SQLITE_CORRUPT] in [sqlite3changeset_next()]) or an ** [SQLITE_NOMEM] in [sqlite3changeset_new()] then an error code corresponding ** to that error is returned by this function. Otherwise, SQLITE_OK is ** returned. This is to allow the following pattern (pseudo-code): *** ** sqlite3changeset_start(); ** while(SQLITE_ROW==sqlite3changeset_next()){ ** // Do something with change. ** } ** rc = sqlite3changeset_finalize(); ** if(rc!=SQLITE_OK) { ** // An error has occurred ** }

label: code-design

67248. ** Allocate nByte bytes of memory.

67249. ** This function is called from within the xConnect() or xCreate() method to ** determine the node-size used by the rtree table being created or connected ** to. If successful, pRtree->iNodeSize is populated and SQLITE_OK returned. ** Otherwise, an SQLite error code is returned. *** If this function is being called as part of an xConnect(), then the rtree ** table already exists. In this case the node-size is determined by inspecting ** the root node of the tree. *** Otherwise, for an xCreate(), use 64 bytes less than the database page-size. ** This ensures that each node is stored on a single database page. If the ** database page-size is so large that more than RTREE_MAXCELLS entries ** would fit in a single node, use a smaller node-size.

67250. 680

67251. File handle for the database file

67252. Generate code that will load into register regOut a value that is ** appropriate for the iIdxCol-th column of index pIdx.

67253. Check for the rbu_count table. If it does not exist, or if an error ** occurs, nPhaseOneStep will be left set to -1.

67254. List of tables in current patch

67255. aiRowLogEst values come from sqlite_stat1

67256. All nFrom paths at the previous level

67257. Information about each column

67258. There already exists a WhereLoop on the list that is better ** than pTemplate, so just ignore pTemplate

67259. Buffer containing string or blob data

67260. IMP: R-61914-48074

67261. Btree

67262. ** Disable MMAP on platforms where it is known to not work

67263. The ram filesystem has no write behind ** so it is ordered

67264. Canonical filename

67265. Opcode: Concat P1 P2 P3 * * * Synopsis: r[P3]=r[P2]+r[P1] *** Add the text in register P1 onto the end of the text in ** register P2 and store the result in register P3. ** If either the P1 or P2 text are NULL then store NULL in P3. *** P3 = P2 || P1 *** It is illegal for P1 and P3 to be the same register. Sometimes, ** if P3 is the same register as P2, the implementation is able ** to avoid a memcpy().

67266. 7 -> NOTINDEXED

67267. Number of dimensions

67268. ** Clear the column names from every VIEW in database idx.

67269. ** Return true if it desirable to avoid allocating a new page cache ** entry. *** If memory was allocated specifically to the page cache using ** SQLITE_CONFIG_PAGECACHE but that memory has all been used, then ** it is desirable to avoid allocating a new page cache entry because ** presumably SQLITE_CONFIG_PAGECACHE was suppose to be sufficient ** for all page cache needs and we should not need to spill the ** allocation onto the heap. *** Or, the heap is used for all page cache memory but the heap is ** under memory pressure, then again it is desirable to avoid ** allocating a new page cache entry in order to avoid stressing ** the heap even further.

67270. ** Streaming version of sqlite3changeset_start().

67271. The Btree to which this cursor belongs

67272. Forward references to VFS methods

67273. Figure out the name of the primary key index for the current table. ** This is needed for the argument to "PRAGMA index_xinfo". Set ** zIdx to point to a null-terminated string containing this name.

67274. ** Add a single new WhereTerm entry to the WhereClause object pWC. ** The new WhereTerm object is constructed from Expr p and with wtFlags. ** The index in pWC->a[] of the new WhereTerm is returned on success. ** 0 is returned if the new WhereTerm could not be added due to a memory ** allocation error. The memory allocation failure will be recorded in ** the db->mallocFailed flag so that higher-level functions can detect it. *** This routine will increase the size of the pWC->a[] array as necessary. ** If the wtFlags argument includes TERM_DYNAMIC, then responsibility ** for freeing the expression p is assumed by the WhereClause object pWC. ** This is true even if this routine fails to allocate a new WhereTerm. *** WARNING: This routine might reallocate the space used to store ** WhereTerms. All pointers to WhereTerms should be invalidated after ** calling this routine. Such pointers may be reinitialized by referencing ** the pWC->a[] array.

67275. SQL_CHOMP_SEGDIR ** Update the start_block (:1) and root (:2) fields of the %_segdir ** entry located on absolute level :3 with index :4.

67553. Has no GROUP BY clause

67554. Number of bytes of prefix compression

67555. !defined(SQLITE_OMIT_TRIGGER)

67556. The three function arguments

67557. Partial index inappropriate for this query

67558. Jump to the appropriate pragma handler

67559. ** The following are allowed values for Vdbe.magic

67560. Use native byte order

67561. Column index on lhs of IN operator

67562. ** Look up an index by name. Or, if the name of a WITHOUT ROWID table ** is supplied instead, find the PRIMARY KEY index for that table.

67563. SQLite assumes that xFullPathname() nul-terminates the output buffer ** even if it returns an error.

67564. Table holding the result of the SELECT

67565. ** The most recently coded instruction was an OP_Column to retrieve the ** i-th column of table pTab. This routine sets the P4 parameter of the ** OP_Column to the default value, if any. ** ** The default value of a column is specified by a DEFAULT clause in the ** column definition. This was either supplied by the user when the table ** was created, or added later to the table definition by an ALTER TABLE ** command. If the latter, then the row-records in the table btree on disk ** may not contain a value for the column and the default value, taken ** from the P4 parameter of the OP_Column instruction, is returned instead. ** If the former, then all row-records are guaranteed to include a value ** for the column and the P4 value is not required. ** ** Column definitions created by an ALTER TABLE command may only have ** literal default values specified: a number, null or a string. (If a more ** complicated default expression value was provided, it is evaluated ** when the ALTER TABLE is executed and one of the literal values written ** into the sqlite_master table.) ** ** Therefore, the P4 parameter is only required if the default value for ** the column is a literal number, string or null. The sqlite3ValueFromExpr() ** function is capable of transforming these types of expressions into ** sqlite3_value objects. ** ** If parameter iReg is not negative, code an OP_RealAffinity instruction ** on register iReg. This is used when an equivalent integer value is ** stored in place of an 8-byte floating point value in order to save ** space.

67566. Ticket 2ea2425d34be

67567. ** The following macro defines an initializer for an sqlite3_vfs object. ** The name of the VFS is NAME. The pAppData is a pointer to a pointer ** to the "finder" function. (pAppData is a pointer to a pointer because ** silly C90 rules prohibit a void* from being cast to a function pointer ** and so we have to go through the intermediate pointer to avoid problems ** when compiling with -pedantic-errors on GCC.) ** ** The FINDERT parameter to this macro is the name of the pointer to the ** finder-function. The finder-function returns a pointer to the ** sqlite_io_methods object that implements the desired locking ** behaviors. See the division above that contains the IOMETHODS ** macro for addition information on finder-functions. ** ** Most finders simply return a pointer to a fixed sqlite3_io_methods ** object. But the "autolockIoFinder" available on MacOSX does a little ** more than that; it looks at the filesystem type that hosts the ** database file and tries to choose an locking method appropriate for ** that filesystem time.

67568. Number of significant digits returned

67569. True after mutexes are initialized

67570. Index of the first hidden column

67571. Define the yytestcase() macro to be a no-op if is not already defined ** otherwise. ** ** Applications can choose to define yytestcase() in the %include section ** to a macro that can assist in verifying code coverage. For production ** code the yytestcase() macro should be turned off. But it is useful ** for testing.

67754. The next table maps tokens (terminal symbols) into fallback tokens. ** If a construct like the following: ** * * %fallback ID X Y Z. ** * * appears in the grammar, then ID becomes a fallback token for X, Y, ** and Z. Whenever one of the tokens X, Y, or Z is input to the parser ** but it does not parse, the type of the token is changed to ID and ** the parse is retried before an error is thrown. ** * * This feature can be used, for example, to cause some keywords in a language ** to revert to identifiers if they keyword does not apply in the context where ** it appears.
67755. ** Token types used by the sqlite3_complete() routine. See the header ** comments on that procedure for additional information.
67756. Jump here to continue with next record
67757. Add the "eNNN" suffix
67758. Pointer type when MEM_Term|MEM_Subtype|MEM_Null
67759. Register holding an index key
67760. Number of pages still on the free-list
67761. The VDBE cursor for the table
67762. One byte past the end of usable data
67763. A view
67764. Dummy argument used with tokenizer
67765. Buffer to load data from wal file into
67766. ** Return the length of the data corresponding to the supplied serial-type.
67767. True if statement may throw an ABORT exception
67768. Remove the node from the in-memory hash table and link it into ** the Rtree.pDeleted list. Its contents will be re-inserted later on.
67769. Number of elements in argv[]
67770. Pointer to write buffer
67771. Current offset within aInput[]

67772. ** The default MMAP_SIZE is zero on all platforms. Or, even if a larger ** default MMAP_SIZE is specified at compile-time, make sure that it does ** not exceed the maximum mmap size.

67773. Called during startup to register a UDF with SQLite

67774. deadman switch

67775. True to use xFetch()

67776. Token pList/nList corresponds to

67777. Opcode: VCreate P1 P2 * * * * * P2 is a register that holds the name of a virtual table in database ** P1. Call the xCreate method for that table.

67778. Index structure corresponding to u1.zIndexedBy

67779. Database Name Table Name

67780. First argument passed to xFilter

67781. The whole SELECT statement

67782. Page iter.iLeaf must now be the rightmost leaf-page in the segment

67783. ** Return the number of cursors open on pBt. This is for use ** in assert() expressions, so it is only compiled if NDEBUG is not ** defined. ** * Only write cursors are counted if wrOnly is true. If wrOnly is ** false then all cursors are counted. ** * For the purposes of this routine, a cursor is any cursor that ** is capable of reading or writing to the database. Cursors that ** have been tripped into the CURSORFAULT state are not counted.

67784. Opcode: IdxRowid P1 P2 * * * * * Synopsis: r[P2]=rowid ** * Write into register P2 an integer which is the last entry in the record at ** the end of the index key pointed to by cursor P1. This integer should be ** the rowid of the table entry to which this index entry points. ** * See also: Rowid, MakeRecord.

67785. Number of fragments in this snippet

67786. FROM clause does not contain a real table

67787. ** An object of this type is used internally as an abstraction for ** input data. Input data may be supplied either as a single large buffer ** (e.g. sqlite3changeset_start()) or using a stream function (e.g. ** sqlite3changeset_start_strm()).

67788. (316) foreach_clause ::= FOR EACH ROW

67789. The "real" underlying VFS

67790. This is either a full-table scan (ePlan==FTS5_PLAN_SCAN) or a lookup ** by rowid (ePlan==FTS5_PLAN_ROWID).

67791. In this case, the RHS is the ROWID of table b-tree and so we also ** know that the RHS is non-NULL. Hence, we combine steps 3 and 4 ** into a single opcode.

67792. One or both operands are NULL

67793. Name of the file containing the BTree database

67794. pParent->pLeft==this or pParent->pRight==this

67795. ** Bits that make up the "idxNum" parameter passed indirectly by ** xBestIndex() to xFilter().

67796. **comment:** ** A version of printf() that understands %lld. Used for debugging. ** The printf() built into some versions of windows does not understand %lld ** and segfaults if you give it a long long int.

label: code-design

67797. One for every 32KB page in the wal-index

67798. At least one of the two values is a number

67799. ** Return the total number of segments in index structure pStruct. This ** function is only ever used as part of assert() conditions.

67800. Obscure case for non-leaf-data trees: If the cell at pCell was ** previously stored on a leaf node, and its reported size was 4 ** bytes, then it may actually be smaller than this ** (see btreeParseCellPtr(), 4 bytes is the minimum size of ** any cell). But it is important to pass the correct size to ** insertCell(), so reparse the cell now. ** * This can only happen for b-trees used to evaluate "IN (SELECT ...)" ** and WITHOUT ROWID tables with exactly one column which is the ** primary key.

67801. FTS Table pointer

67802. The last prior entry

67803. ** Load the sqlite3.iSysErrno field if that is an appropriate thing ** to do based on the SQLite error code in rc.

67804. 294

67805. EVIDENCE-OF: R-08404-60887 There are three arguments to ** SQLITE_CONFIG_SCRATCH: A pointer an 8-byte aligned memory buffer from ** which the scratch allocations will be drawn, the size of each scratch ** allocation (sz), and the maximum number of scratch allocations (N).

67806. **comment:** The following macro is used to suppress compiler warnings.

label: code-design

67807. Size of the database file

67808. Information about this WHERE

67809. ** Given that zWal points to a buffer containing a wal file name passed to ** either the xOpen() or xAccess() VFS method, return a pointer to the ** file-handle opened by the same database connection on the corresponding ** database file.

67810. 39==sqlite3LogEst(15)

67811. ** Head and tail of a linked list of all outstanding allocations

67812. Number of open viewpoints (0 -> none)

67813. Raw hash value of the key

67814. ** Write the supplied master journal name into the journal file for pager ** pPager at the current location. The master journal name must be the last ** thing written to a journal file. If the pager is in full-sync mode, the ** journal file descriptor is advanced to the next sector boundary before ** anything is written. The format is: ** * + 4 bytes: PAGER_MJ_PGNO. ** + N bytes: Master journal filename in utf-8. ** + 4 bytes: N (length of master journal name in bytes, no null-terminator). ** + 4 bytes: Master journal name checksum. ** + 8 bytes: aJournalMagic[]. ** * The master journal page checksum is the sum of the bytes in the master ** journal name, where each byte is interpreted as a signed 8-bit integer. ** * If zMaster is a NULL pointer (occurs for a single database transaction), ** this call is a no-op.

67815. Second sorted list to be merged

67816. ESCAPE

67817. ** Historically, SQLite has used both the LockFile and LockFileEx functions. ** When the LockFile function was used, it was always expected to fail ** immediately if the lock could not be obtained. Also, it always expected to ** obtain an exclusive lock. These flags are used with the LockFileEx function ** and reflect those expectations; therefore, they should not be changed.

67818. IMPLEMENTATION-OF: R-26801-64137 If the xInit() method is NULL, then the ** built-in default page cache is used instead of the application defined ** page cache.

67819. Less than 19 digits, so we know that it fits in 64 bits

67820. The principle used to locate the table name in the CREATE TABLE ** statement is that the table name is the first non-space token that ** is immediately followed by a TK_LP or TK_USING token.

67821. **comment:** #define sqliteHashKeysize(E) ((E)->nKey) // NOT USED

label: code-design

67822. The result set must be the special operator **

67823. ** The following structure describes the FROM clause of a SELECT statement. ** Each table or subquery in the FROM clause is a separate element of ** the SrcList.a[] array. ** * With the addition of multiple database support, the following structure ** can also be used to describe a particular table such as the table that ** is modified by an INSERT, DELETE, or UPDATE statement. In standard SQL, ** such a table must be a simple name: ID. But in SQLite, the table can ** now be identified by a database name, a dot, then the table name: ID.ID. ** * The jointype starts out showing the join type between the current table ** and the next table on the list. The parser builds the list this way. ** But sqlite3SrcListShiftJoinType() later shifts the jointypes so that each ** jointype expresses the join between the table and the previous table. ** * In the colUsed field, the high-order bit (bit 63) is set if the table ** contains more than 63 columns and the 64-th or later column is used.

67824. Term.pExpr contains a correlated sub-query

67825. If a prior error occurred, report that error again.

67826. **comment:** ** OMIT_TEMPDB is set to 1 if SQLITE OMIT_TEMPDB is defined, or 0 ** afterward. Having this macro allows us to cause the C compiler ** to omit code used by TEMP tables without messy #ifndef statements.

If 1, the new.* table. ** ** Parameter tr_tm must be a mask with one or both of the TRIGGER_BEFORE ** and TRIGGER_AFTER bits set. Values accessed by BEFORE triggers are only ** included in the returned mask if the TRIGGER_BEFORE bit is set in the ** tr_tm parameter. Similarly, values accessed by AFTER triggers are only ** included in the returned mask if the TRIGGER_AFTER bit is set in tr_tm.
67954. Original number of pages in file
67955. If pList==0, it means this routine was called to make a primary ** key out of the last column added to the table under construction. ** So create a fake list to simulate this.
67956. Register holding NULL status. See notes
67957. **comment:** ** 2007 August 14 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **

** SQLite will use the standard C-library malloc/realloc/free interface ** to obtain the memory it needs. ** ** This file contains implementations of the low-level memory allocation ** routines specified in the sqlite3_mem_methods object. The content of ** this file is only used if SQLITE_SYSTEM_MALLOC is defined. The ** SQLITE_SYSTEM_MALLOC macro is defined automatically if neither the ** SQLITE_MEMDEBUG nor the SQLITE_WIN32_MALLOC macros are defined. The ** default configuration is to use memory allocation routines in this ** file. ** ** C-preprocessor macro summary: ** ** HAVE_MALLOC_USABLE_SIZE The configure script sets this symbol if ** the malloc_usable_size() interface exists ** on the target platform. Or, this symbol ** can be set manually, if desired. ** If an equivalent interface exists by ** a different name, using a separate -D ** option to rename it. ** ** SQLITE WITHOUT_ZONEMALLOC Some older macs lack support for the zone ** memory allocator. Set this symbol to enable ** building on older macs. ** ** SQLITE WITHOUT_MSIZE Set this symbol to disable the use of ** _msize() on windows systems. This might ** be necessary when compiling for Delphi, ** for example.
label: code-design
67958. ** Check that argument nHeight is less than or equal to the maximum ** expression depth allowed. If it is not, leave an error message in ** pParse.
67959. ** Interpret the given string as a temp db location. Return 1 for file ** backed temporary databases, 2 for the Red-Black tree in memory database ** and 0 to use the compile-time default.
67960. ** This routine sets the state to CURSORFAULT and the error ** code to errCode for every cursor on any BtShared that pBtree ** references. Or if the writeOnly flag is set to 1, then only ** trip write cursors and leave read cursors unchanged. ** ** Every cursor is a candidate to be tripped, including cursors ** that belong to other database connections that happen to be ** sharing the cache with pBtree. ** ** This routine gets called when a rollback occurs. If the writeOnly ** flag is true, then only write-cursors need be tripped - read-only ** cursors save their current positions so that they may continue ** following the rollback. Or, if writeOnly is false, all cursors are ** tripped. In general, writeOnly is false if the transaction being ** rolled back modified the database schema. In this case b-tree root ** pages may be moved or deleted from the database altogether, making ** it unsafe for read cursors to continue. ** ** If the writeOnly flag is true and an error is encountered while ** saving the current position of a read-only cursor, all cursors, ** including all read-cursors are tripped. ** ** SQLITE_OK is returned if successful, or if an error occurs while ** saving a cursor position, an SQLite error code.
67961. Set rCostIdx to the cost of visiting selected rows in index. Add ** it to pNew->rRun, which is currently set to the cost of the index ** seek only. Then, if this is a non-covering index, add the cost of ** visiting the rows in the main table.
67962. nothing to do if the path is NULL, :auto: or matches the existing path
67963. Number of key columns in pIndex
67964. min(maxLocal,127)
67965. We should never write to the journal file the page that ** contains the database locks. The following assert verifies ** that we do not.
67966. Free memory immediately, rather than waiting on sqlite3_finalize()
67967. ** Move the write position of the WAL back to the point identified by ** the values in the aWalData[] array. aWalData must point to an array ** of WAL_SAVEPOINT_NDATA u32 values that has been previously populated ** by a call to WalSavepoint().
67968. The trigger that this step is a part of
67969. Cannot have C without B
67970. True if nTotalRow/aTotalSize[] are valid
67971. Current index in aLeft
67972. ** Table p is a virtual table. This function moves all elements in the ** p->pVTable list to the sqlite3.pDisconnect lists of their associated ** database connections to be disconnected at the next opportunity. ** Except, if argument db is not NULL, then the entry associated with ** connection db is left in the p->pVTable list.
67973. Insert into rbu_tmp_.\$zDataTbl
67974. Normally sqlite3SelectExpand() will be called first and will have ** already expanded this SELECT. However, if this is a subquery within ** an expression, sqlite3ResolveExprNames() will be called without a ** prior call to sqlite3SelectExpand(). When that happens, let ** sqlite3SelectPrep() do all of the processing for this SELECT. ** sqlite3SelectPrep() will invoke both sqlite3SelectExpand() and ** this routine in the correct order.
67975. WAL savepoint context
67976. Token:
67977. Use SQLITE_ENABLE_COMMENTS to enable generation of extra comments on ** each VDBE opcode. ** ** Use the SQLITE_ENABLE_MODULE_COMMENTS macro to see some extra no-op ** comments in VDBE programs that show key decision points in the code ** generator.
67978. 52
67979. Upper bound on the range. ex: "x<455" Might be NULL
67980. The virtual database engine
67981. Index of langid=x constraint, if present
67982. ** Set the bit number pgno in the PagerSavepoint.pInSavepoint ** bitvecs of all open savepoints. Return SQLITE_OK if successful ** or SQLITE_NOMEM if a malloc failure occurs.

67983. 0x7FFFFFFF is the hard limit for the number of pages in a database ** file. By passing this as the number of pages to copy to ** sqlite3_backup_step(), we can guarantee that the copy finishes ** within a single call (unless an error occurs). The assert() statement ** checks this assumption - (p->rc) should be set to either SQLITE_DONE ** or an error code.

67984. Get the database meta information. ** ** Meta values are as follows: ** meta[0] Schema cookie. Changes with each schema change. ** meta[1] File format of schema layer. ** meta[2] Size of the page cache. ** meta[3] Largest rootpage (auto/incr_vacuum mode) ** meta[4] Db text encoding. 1=UTF-8 2=UTF-16LE 3=UTF-16BE ** meta[5] User version ** meta[6] Incremental vacuum mode ** meta[7] unused ** meta[8] unused ** meta[9] unused ** ** Note: The #defined SQLITE_UTF* symbols in sqliteInt.h correspond to ** the possible values of meta[4].

67985. 1st argument to callback

67986. Make a copy of an sqlite3_value object

67987. ** This routine deletes the RtreeGeomCallback object that was attached ** one of the SQL functions create by sqlite3_rtree_geometry_callback() ** or sqlite3_rtree_query_callback(). In other words, this routine is the ** destructor for an RtreeGeomCallback objecct. This routine is called when ** the corresponding SQL function is deleted.

67988. Mutex configuration options are only available in a threadsafe ** compile.

67989. Right hand side of comparison

67990. Type of the new cursor

67991. SQLITE_OMIT_VIRTUALTABLE

67992. First byte of token

67993. ***** Begin file backup.c *****

67994. ** The rbu_state table is used to save the state of a partially applied ** update so that it can be resumed later. The table consists of integer ** keys mapped to values as follows: ** ** RBU_STATE_STAGE: ** May be set to integer values 1, 2, 4 or 5. As follows: ** 1: the *-rbu file is currently under construction. ** 2: the *-rbu file has been constructed, but not yet moved ** to the *-wal path. ** 4: the checkpoint is underway. ** 5: the rbu update has been checkpointed. ** ** RBU_STATE_TBL: ** Only valid if STAGE==1. The target database name of the table ** currently being written. ** ** RBU_STATE_IDX: ** Only valid if STAGE==1. The target database name of the index ** currently being written, or NULL if the main table is currently being ** updated. ** ** RBU_STATE_ROW: ** Only valid if STAGE==1. Number of rows already processed for the current ** table/index. ** ** RBU_STATE_PROGRESS: ** Trbul number of sqlite3rbu_step() calls made so far as part of this ** rbu update. ** ** RBU_STATE_CKPT: ** Valid if STAGE==4. The 64-bit checksum associated with the wal-index ** header created by recovering the *-wal file. This is used to detect ** cases when another client appends frames to the *-wal file in the ** middle of an incremental checkpoint (an incremental checkpoint cannot ** be continued if this happens). ** ** RBU_STATE_COOKIE: ** Valid if STAGE==1. The current change-counter cookie value in the ** target db file. ** ** RBU_STATE_OALSZ: ** Valid if STAGE==1. The size in bytes of the *-oal file.

67995. The subquery

67996. True for "patchset", 0 for "changeset"

67997. Current number of cells in pNode

67998. from vdbeSortSubtaskMain()

67999. Language id to query

68000. 185

68001. ** CAPI3REF: Find the next prepared statement ** METHOD: sqlite3 ** ** ^This interface returns a pointer to the next [prepared statement] after ** pStmt associated with the [database connection] pDb. ^If pStmt is NULL ** then this interface returns a pointer to the first prepared statement ** associated with the database connection pDb. ^If no prepared statement ** satisfies the conditions of this routine, it returns NULL. ** ** The [database connection] pointer D in a call to ** [sqlite3_next_stmt(D,S)] must refer to an open database ** connection and in particular must not be a NULL pointer.

68002. Length of the next token token

68003. Zero the output variables in case an error occurs. If this session ** object is already in the error state (sqlite3_session.rc != SQLITE_OK), ** this call will be a no-op.

68004. Which columns are used by this index. 1st is 0

68005. Array of flags, set on NOT NULL columns

68006. 1500

68007. ** End of MatchinfoBuffer code. *****

68008. Log the error, but continue normal operation using xRead/xWrite

68009. ** Return a static string containing the name corresponding to the error code ** specified in the argument.

68010. 480

68011. 0x20 .. 0x2F

68012. De-reference and close our copy of the shared memory handle

68013. **comment:** Sync the journal file and write all dirty pages to the database. ** If the atomic-update optimization is being used, this sync will not ** create the journal file or perform any real IO. ** ** Because the change-counter page was just modified, unless the ** atomic-update optimization is used it is almost certain that the ** journal requires a sync here. However, in locking_mode=exclusive ** on a system under memory pressure it is just possible that this is ** not the case. In this case it is likely enough that the redundant ** xSync() call will be changed to a no-op by the OS anyhow.

68089. User data parameter
68090. For iterating through doclist index
68091. ALL
68092. ** CAPI3REF: Obtain The Primary Key Definition Of A Table ** ** For each modified table, a changeset includes the following: ** ** ** The number of columns in the table, and ** Which of those columns make up the tables PRIMARY KEY. ** ** ** This function is used to find which columns comprise the PRIMARY KEY of ** the table modified by the change that iterator pIter currently points to. ** If successful, *pabPK is set to point to an array of nCol entries, where ** nCol is the number of columns in the table. Elements of *pabPK are set to ** 0x01 if the corresponding column is part of the tables primary key, or ** 0x00 if it is not. ** ** If argument pnCol is not NULL, then *pnCol is set to the number of columns ** in the table. ** ** If this function is called when the iterator does not point to a valid ** entry, SQLITE_MISUSE is returned and the output variables zeroed. Otherwise, ** SQLITE_OK is returned and the output variables populated as described ** above.
68093. Full size
68094. ** Find the current time (in Universal Coordinated Time). Write into *piNow ** the current time and date as a Julian Day number times 86_400_000. In ** other words, write into *piNow the number of milliseconds since the Julian ** epoch of noon in Greenwich on November 24, 4714 B.C according to the ** proleptic Gregorian calendar. *** On success, return SQLITE_OK. Return SQLITE_ERROR if the time and date ** cannot be found.

68095. Compute the comparison permutation and keyinfo that is used with ** the permutation used to determine if the next ** row of results comes from selectA or selectB. Also add explicit ** collations to the ORDER BY clause terms so that when the subqueries ** to the right and the left are evaluated, they use the correct ** collation.
 68096. ** Restore the state of the PRNG to the last state saved using ** PRNG_SAVE. If PRNG_SAVE has never before been called, then ** this verb acts like PRNG_RESET.
 68097. Left-most of SELECT of a compound
 68098. ***** Begin file pragma.h *****
 68099. ** Free a single node of an expression tree.
 68100. Last chance verification. If the sector size isn't a multiple of 512 ** then it isn't valid.
 68101. **comment:** ** Disable a term in the WHERE clause. Except, do not disable the term ** if it controls a LEFT OUTER JOIN and it did not originate in the ON ** or USING clause of that join. ** ** Consider the term t2.z='ok' in the following queries: ** ** (1) SELECT * FROM t1 LEFT JOIN t2 ON t1.a=t2.x WHERE t2.z='ok' ** (2) SELECT * FROM t1 LEFT JOIN t2 ON t1.a=t2.x AND t2.z='ok' ** (3) SELECT * FROM t1, t2 WHERE t1.a=t2.x AND t2.z='ok' ** ** The t2.z='ok' is disabled in the (2) because it originates ** in the ON clause. The term is disabled in (3) because it is not part ** of a LEFT OUTER JOIN. In (1), the term is not disabled. ** ** Disabling a term causes that term to not be tested in the inner loop ** of the join. Disabling is an optimization. When terms are satisfied ** by indices, we disable them to prevent redundant tests in the inner ** loop. We would get the correct results if nothing were ever disabled, ** but joins might run a little slower. The trick is to disable as much ** as we can without disabling too much. If we disabled in (1), we'd get ** the wrong answer. See ticket #813. ** ** If all the children of a term are disabled, then that term is also ** automatically disabled. In this way, terms get disabled if derived ** virtual terms are tested first. For example: ** ** x GLOB 'abc*' AND x>='abc' AND x<'acd' ** _____ / ____ / ____ / ** parent child1 child2 ** ** Only the parent term was in the original WHERE clause. The child1 ** and child2 terms were added by the LIKE optimization. If both of ** the virtual child terms are valid, then testing of the parent can be ** skipped. ** ** Usually the parent term is marked as TERM_CODED. But if the parent ** term was originally TERM_LIKE, then the parent gets TERM_LIKECOND instead. ** The TERM_LIKECOND marking indicates that the term should be coded inside ** a conditional such that is only evaluated on the second pass of a ** LIKE-optimization loop, when scanning BLOBS instead of strings.

 68139. Pager object associated with page pPg
 68140. Otherwise, the argument is a column name.
 68141. Buffer to deserialize from
 68142. **comment:** ***** Beginning of RBU VFS shim methods. The VFS shim modifies the behaviour ** of a standard VFS in the following ways: ** ** 1. Whenever the first page of a main database file is read or ** written, the value of the change-counter cookie is stored in ** rbu_file.iCookie. Similarly, the value of the "write-version" ** database header field is stored in rbu_file.iWriteVer. This ensures ** that the values are always trustworthy within an open transaction. ** ** 2. Whenever an SQLITE_OPEN_WAL file is opened, the (rbu_file.pWalFd) ** member variable of the associated database file descriptor is set ** to point to the new file. A mutex protected linked list of all main ** db fds opened using a particular RBU VFS is maintained at ** rbu_vfs.pMain to facilitate this. ** ** 3. Using a new file-control "SQLITE_FCNTL_RBU", a main db rbu_file ** object can be marked as the target database of an RBU update. This ** turns on the following extra special behaviour: ** ** 3a. If xAccess() is called to check if there exists a *-wal file ** associated with an RBU target database currently in RBU_STAGE_OAL ** stage (preparing the *-oal file), the following special handling ** applies: ** ** * if the *-wal file does exist, return SQLITE_CANTOPEN. An RBU ** target database may not be in wal mode already. ** ** * if the *-wal file does not exist, set the output parameter to ** non-zero (to tell SQLite that it does exist) anyway. ** ** Then, when xOpen() is called to open the *-wal file associated with ** the RBU target in RBU_STAGE_OAL stage, instead of opening the *-wal ** file, the rbu vfs opens the corresponding *-oal file instead. ** ** 3b. The *-shm pages returned by xShmMap() for a target db file in ** RBU_STAGE_OAL mode are actually stored in heap memory. This is to ** avoid creating a *-shm file on disk. Additionally, xShmLock() calls ** are no-ops on target database files in RBU_STAGE_OAL mode. This is ** because assert() statements in

some VFS implementations fail if ** xShmLock() is called before xShmMap(). *** 3c. If an EXCLUSIVE lock is attempted on a target database file in any ** mode except RBU_STAGE_DONE (all work completed and checkpointed), it ** fails with an SQLITE_BUSY error. This is to stop RBU connections ** from automatically checkpointing a *-wal (or *-oal) file from within ** sqlite3_close(). *** 3d. In RBU_STAGE_CAPTURE mode, all xRead() calls on the wal file, and ** all xWrite() calls on the target database file perform no IO. ** Instead the frame and page numbers that would be read and written ** are recorded. Additionally, successful attempts to obtain exclusive ** xShmLock() WRITER, CHECKPOINTER and READ0 locks on the target ** database file are recorded. xShmLock() calls to unlock the same ** locks are no-ops (so that once obtained, these locks are never ** relinquished). Finally, calls to xSync() on the target database ** file fail with SQLITE_INTERNAL errors.

68301. **comment:** ** Adjust settings of the pager to those specified in the pgFlags parameter. *** The "level" in pgFlags & PAGER_SYNCHRONOUS_MASK sets the robustness ** of the database to damage due to OS crashes or power failures by ** changing the number of syncs() when writing the journals. ** There are four levels: *** OFF sqlite3OsSync() is never called. This is the default ** for temporary and transient files. *** NORMAL The journal is synced once before writes begin on the ** database. This is normally adequate protection, but ** it is theoretically possible, though very unlikely, ** that an inopportune power failure could leave the journal ** in a state which would cause damage to the database ** when it is rolled back. *** FULL The journal is synced twice before writes begin on the ** database (with some additional information - the nRec field ** of the journal header - being written in between the two ** syncs). If we assume that writing a ** single disk sector is atomic, then this mode provides ** assurance that the journal will not be corrupted to the ** point of causing damage to the database during rollback. *** EXTRA This is like FULL except that is also syncs the directory ** that contains the rollback journal after the rollback ** journal is unlinked. *** The above is for a rollback-journal mode. For WAL mode, OFF continues ** to mean that no syncs ever occur. NORMAL means that the WAL is synced ** prior to the start of checkpoint and that the database file is synced ** at the conclusion of the checkpoint if the entire content of the WAL ** was written back into the database. But no sync operations occur for ** an ordinary commit in NORMAL mode with WAL. FULL means that the WAL ** file is synced following each commit operation, in addition to the ** syncs associated with NORMAL. There is no difference between FULL ** and EXTRA for WAL mode. *** Do not confuse synchronous=FULL with SQLITE_SYNC_FULL. The ** SQLITE_SYNC_FULL macro means to use the Mac OSX-style full-fsync ** using fcnl(F_FULLFSYNC). SQLITE_SYNC_NORMAL means to do an ** ordinary fsync() call. There is no difference between SQLITE_SYNC_FULL ** and SQLITE_SYNC_NORMAL on platforms other than Mac OSX. But the ** synchronous=FULL versus synchronous=NORMAL setting determines when ** the xSync primitive is called and is relevant to all platforms. *** Numeric values associated with these states are OFF==1, NORMAL==2, ** and FULL==3.

label: code-design

68302. Legacy behavior (sqlite3_close()) behavior is to return ** SQLITE_BUSY if the connection can not be closed immediately.

68303. xSectorSize

68304. EVIDENCE-OF: R-55269-29598 The localtime_r() C function normally only ** works for years between 1970 and 2037. For dates outside this range, ** SQLite attempts to map the year into an equivalent year within this ** range, do the calculation, then map the year back.

68305. Jump to this label to skip a row

68306. Set nLoad4 to the value of (4^nOther) for the next iteration of the ** for-loop. Except, limit the value to 2^24 to prevent it from ** overflowing the 32-bit integer it is stored in.

68307. The simple case - no more than one database file (not counting the ** TEMP database) has a transaction active. There is no need for the ** master-journal. *** If the return value of sqlite3BtreeGetFilename() is a zero length ** string, it means the main database is :memory: or a temp file. In ** that case we do not support atomic multi-file commits, so use the ** simple case then too.

68308. 1220

68309. Affinity must be the same on all columns

68310. OUT. True if change is indirect

68311. At this point, okToChngToIN is true if original pTerm satisfies ** case 1. In that case, construct a new virtual term that is ** pTerm converted into an IN operator.

68312. Write the new expression node here

68313. Maximum of 4 fragments per snippet

68314. The first to increment to 1 does actual initialization

68315. #include "fts3Int.h"

68316. Only sort the current set of entries if they need it

68317. 171

68318. default size is approx 4 bytes

68319. Size of each scratch buffer

68320. ** Return true (non-zero) if we are running under WinNT, Win2K, WinXP, ** or WinCE. Return false (zero) for Win95, Win98, or WinME. *** Here is an interesting observation: Win95, Win98, and WinME lack ** the LockFileEx() API. But we can still statically link against that ** API as long as we don't call it when running Win95/98/ME. A call to ** this routine is used to determine if the host is Win95/98/ME or ** WinNT/2K/XP so that we will know whether or not we can safely call ** the LockFileEx() API.

68321. Expression list to resolve. May be NUL.

68322. Token:

68323. ** Deserialize and return the structure record currently stored in serialized ** form within buffer pData/nData. *** The Fts5Structure.aLevel[] and each Fts5StructureLevel.aSeg[] array ** are over-allocated by one slot. This allows the structure contents ** to be more easily edited. *** If an error occurs, *ppOut is set to NULL and an SQLite error code ** returned. Otherwise, *ppOut is set to point to the new object and ** SQLITE_OK returned.

68324. ** Helper function for fts3ExprIterate() (see below).

68325. ** Convert a schema pointer into the iDb index that indicates ** which database file in db->aDb[] the schema refers to. *** If the same database is attached more than once, the first ** attached database is returned.

68326. FTS index to query

68327. ** This function is a helper function for sqlite3Fts3EvalTestDeferred(). ** Assuming no error occurs or has occurred, It returns non-zero if the ** expression passed as the second argument matches the row that pCsr ** currently points to, or zero if it does not. *** If *pRc is not SQLITE_OK when this function is called, it is a no-op. ** If an error occurs during execution of this function, *pRc is set to ** the appropriate SQLite error code. In this case the returned value is ** undefined.

68328. ** Expression pExpr is one operand of a comparison operator that might ** be useful for indexing. This routine checks to see if pExpr appears ** in any index. Return TRUE (1) if pExpr is an indexed term and return ** FALSE (0) if not. If TRUE is returned, also set aiCurCol[0] to the cursor ** number of the table that is indexed and aiCurCol[1] to the column number ** of the column that is indexed, or XN_EXPR (-2) if an expression is being ** indexed. *** If pExpr is a TK_COLUMN column reference, then this routine always returns ** true even if that particular column is not indexed, because the column ** might be added to an automatic index later.

68329. IMPLEMENTATION-OF: R-62028-47212 All calls obtain an exclusive ** "checkpoint" lock on the database file.

68330. ** Set the "type" of an allocation.

68331. ** Print a single opcode. This routine is used for debugging only.

68332. Update or delete the input segments

68333. WinCE has no concept of a relative pathname, or so I am told.

68334. **comment:** As the winMutexInit() and winMutexEnd() functions are called as part ** of the sqlite3_initialize() and sqlite3_shutdown() processing, the ** "interlocked" magic used here is probably not strictly necessary.

label: code-design

68335. Current entry in aPage[]

68336. No affinity ever needs to be (or should be) applied to a value ** from the RHS of an "? IN (SELECT ...)" expression. The ** sqlite3FindInIndex() routine has already ensured that the ** affinity of the comparison has been applied to the value.

68337. Depth of the SAVEPOINT stack

68338. True if the transaction counter changed

68339. An AS clause always takes first priority

68340. **comment:** Set the text that the regular expression operates on to a NULL ** pointer. This is not really necessary, but it is tidier than ** leaving the regular expression object configured with an invalid ** pointer after this function returns.

label: code-design

68341. Number of columns in pIdx. "N"

68342. Key content for indexes. NULL for tables

68343. The key we are searching for

68344. _FTSINT_H

68345. ** Allocate an instance of the default tokenizer ("simple") at ** Fts5Config.pTokenizer. Return SQLITE_OK if successful, or an SQLite error ** code if an error occurs.
68346. result set is empty
68347. ** Return the pager associated with a BTree. This routine is used for ** testing and debugging only.
68348. **comment:** If this is a CREATE TABLE xx AS SELECT ..., execute the SELECT ** statement to populate the new table. The root-page number for the ** new table is in register pParse->regRoot. ** ** Once the SELECT has been coded by sqlite3Select(), it is in a ** suitable state to query for the column names and types to be used ** by the new table. ** ** A shared-cache write-lock is not required to write to the new table, ** as a schema-lock must have already been obtained to create it. Since ** a schema-lock excludes all other database users, the write-lock would ** be redundant.
label: code-design
68349. Open the master journal.
68350. If true, write ldidx to disk
68351. Opcode: Multiply P1 P2 P3 * * * Synopsis: r[P3]=r[P1]*r[P2] ** * * * Multiply the value in register P1 by the value in register P2 ** and store the result in register P3. ** If either input is NULL, the result is NULL.

68478. First byte of gap between cell pointers and cell content
68479. **comment:** ** A copy of the following object occurs in the wal-index immediately ** following the second copy of the WalIndexHdr. This object stores ** information used by checkpoint. ** ** nBackfill is the number of frames in the WAL that have been written ** back into the database. (We call the act of moving content from WAL to ** database "backfilling".) The nBackfill number is never greater than ** WalIndexHdr.mxFrame. nBackfill can only be increased by threads ** holding the WAL_CKPT_LOCK lock (which includes a recovery thread). ** However, a WAL_WRITE_LOCK thread can move the value of nBackfill from ** mxFrame back to zero when the WAL is reset. ** ** nBackfillAttempted is the largest value of nBackfill that a checkpoint ** has attempted to achieve. Normally nBackfill==nBackfillAttempted, however ** the nBackfillAttempted is set before any backfilling is done and the ** nBackfill is only set after all backfilling completes. So if a checkpoint ** crashes, nBackfillAttempted might be larger than nBackfill. The ** WalIndexHdr.mxFrame must never be less than nBackfillAttempted. ** ** The aLock[] field is a set of bytes used for locking. These bytes should ** never be read or written. ** ** There is one entry in aReadMark[] for each reader lock. If a reader ** holds read-lock K, then the value in aReadMark[K] is no greater than ** the mxFrame for that reader. The value READMARK_NOT_USED (0xffffffff) ** for any aReadMark[] means that entry is unused. aReadMark[0] is ** a special case; its value is never used and it exists as a place-holder ** to avoid having to offset aReadMark[] index by one. Readers holding ** WAL_READ_LOCK(0) always ignore the entire WAL and read all content ** directly from the database. ** ** The value of aReadMark[K] may only be changed by a thread that ** is holding an exclusive lock on WAL_READ_LOCK(K). Thus, the value of ** aReadMark[K] cannot change while there is a reader is using that mark ** since the reader will be holding a shared lock on WAL_READ_LOCK(K). ** ** The checkpointer may only transfer frames from WAL to database where ** the frame numbers are less than or equal to every aReadMark[] that is ** in use (that is, every aReadMark[j] for which there is a corresponding ** WAL_READ_LOCK(j)). New readers (usually) pick the aReadMark[] with the ** largest value and will increase an unused aReadMark[] to mxFrame if there ** is not already an aReadMark[] equal to mxFrame. The exception to the ** previous sentence is when nBackfill equals mxFrame (meaning that everything ** in the WAL has been backfilled into the database) then new readers ** will choose aReadMark[0] which has value 0 and hence such reader will ** get all their all content directly from the database file and ignore ** the WAL. ** ** Writers normally append new frames to the end of the WAL. However, ** if nBackfill equals mxFrame (meaning that all WAL content has been ** written back into the database) and if no readers are using the WAL ** (in other words, if there are no WAL_READ_LOCK(i) where i>0) then ** the writer will first "reset" the WAL back to the beginning and start ** writing new content beginning at frame 1. ** ** We assume that 32-bit loads are atomic and so no locks are needed in ** order to read from any aReadMark[] entries.

68489. ** This function is called from both BtreeCommitPhaseTwo() and BtreeRollback() ** at the conclusion of a transaction.
68490. ** Run the integrity-check. If no error occurs and the current contents of ** the FTS index are correct, return SQLITE_OK. Or, if the contents of the ** FTS index are incorrect, return SQLITE_CORRUPT_VTAB. ** ** Or, if an error (e.g. an OOM or IO error) occurs, return an SQLite ** error code. ** ** The integrity-check works as follows. For each token and indexed token ** prefix in the document set, a 64-bit checksum is calculated (by code ** in fts3ChecksumEntry()) based on the following: ** ** + The index number (0 for the main index, 1 for the first prefix ** index etc.), ** + The token (or token prefix) text itself, ** + The language-id of the row it appears in, ** + The docid of the row it appears in, ** + The column it appears in, and ** + The tokens position within that column. ** ** The checksums for all entries in the index are XORed together to create ** a single checksum for the entire index. ** ** The integrity-check code calculates the same checksum in two ways: ** ** 1. By scanning the contents of the FTS index, and ** 2. By scanning and tokenizing the content table. ** ** If the two checksums are identical, the integrity-check is deemed to have ** passed.
68491. Sizes of deleted documents
68492. end of the 'extern "C"' block
68493. Array of registers where record is assembled
68494. ePragFlg:
68495. The cell index. First cell is 0
68496. Opcode: ParseSchema P1 ** P4 * ** * Read and parse all entries from the SQLITE_MASTER table of database P1 ** that match the WHERE clause P4. ** ** This opcode invokes the parser to create a new virtual machine, ** then runs the new virtual machine. It is thus a re-entrant opcode.
68497. Cursor open on index being analyzed

68688. ** If there is a "-oal" file in the file-system corresponding to the ** target database in the file-system, delete it. If an error occurs, ** leave an error code and error message in the rbu handle.
68689. Insert is likely an append
68690. ** CAPI3REF: Virtual Table Indexing Information ** KEYWORDS: sqlite3_index_info ** ** The sqlite3_index_info structure and its substructures is used as part ** of the [virtual table] interface to ** pass information into and receive the reply from the [xBestIndex] ** method of a [virtual table module]. The fields under **Inputs** are the ** inputs to xBestIndex and are read-only. xBestIndex inserts its ** results into the **Output** fields. ** ** ^The aConstraint[] array records WHERE clause constraints of the form: ** ** <blockquote>column OP expr</blockquote> ** ** where OP is =, <, <=, >, or >=.)^^(The particular operator is ** stored in aConstraint[].op using one of the ** [SQLITE_INDEX_CONSTRAINT_EQ | SQLITE_INDEX_CONSTRAINT_VALUES].)^^(The index of the column is stored in ** aConstraint[].iColumn.^^(aConstraint[],usable is TRUE if the ** expr on the right-hand side can be evaluated (and thus the constraint ** is usable) and false if it cannot.)^** ** ^The optimizer automatically inverts terms of the form "expr OP column" ** and makes other simplifications to the WHERE clause in an attempt to ** get as many WHERE clause terms into the form shown above as possible. ** ^The aConstraint[] array only reports WHERE clause terms that are ** relevant to the particular virtual table being queried. ** ** ^Information about the ORDER BY clause is stored in aOrderBy[], ** ^Each term of aOrderBy records a column of the ORDER BY clause. ** ** The colUsed field indicates which columns of the virtual table may be ** required by the current scan. Virtual table columns are numbered from ** zero in the order in which they appear within the CREATE TABLE statement ** passed to sqlite3_declare_vtab(). For the first 63 columns (columns 0-62), ** the corresponding bit is set within the colUsed mask if the column may be ** required by SQLite. If the table has at least 64 columns and any column ** to the right of the first 63 is required, then bit 63 of colUsed is also ** set. In other words, column iCol may be required if the expression ** (colUsed & ((sqlite3_uint64)1 << (iCol>=63 ? 63 : iCol))) evaluates to ** non-zero. ** ** The [xBestIndex] method must fill aConstraintUsage[] with information ** about what parameters to pass to xFilter. ^If argvIndex>0 then ** the right-hand side of the corresponding aConstraint[] is evaluated ** and becomes the argvIndex-th entry in argv. ^If aConstraintUsage[],omit ** is true, then the constraint is assumed to be fully handled by the ** virtual table and is not checked again by SQLite.)^** ** ^The idxNum and idxPtr values are recorded and passed into the ** [xFilter] method. ** ^[sqlite3_free()] is used to free idxPtr if and only if ** needToFreeIdxPtr is true. ** ** ^The orderByConsumed means that output from [xFilter]/[xNext] will occur in ** the correct order to satisfy the ORDER BY clause so that no separate ** sorting step is required. ** ** ^The estimatedCost value is an estimate of the cost of a particular ** strategy. A cost of N indicates that the cost of the strategy is similar ** to a linear scan of an SQLite table with N rows. A cost of log(N) ** indicates that the expense of the operation is similar to that of a ** binary search on a unique indexed field of an SQLite table with N rows. ** ** ^The estimatedRows value is an estimate of the number of rows that ** will be returned by the strategy. ** ** The xBestIndex method may optionally populate the idxFlags field with a ** mask of SQLITE_INDEX_SCAN_* flags. Currently there is only one such flag - ** SQLITE_INDEX_SCAN_UNIQUE. If the xBestIndex method sets this flag, SQLite ** assumes that the strategy may visit at most one row. ** ** Additionally, if xBestIndex sets the SQLITE_INDEX_SCAN_UNIQUE flag, then ** SQLite also assumes that if a call to the xUpdate() method is made as ** part of the same statement to delete or update a virtual table row and the ** implementation returns SQLITE_CONSTRAINT, then there is no need to rollback ** any database changes. In other words, if the xUpdate() returns ** SQLITE_CONSTRAINT, the database contents must be exactly as they were ** before xUpdate was called. By contrast, if SQLITE_INDEX_SCAN_UNIQUE is not ** set and xUpdate returns SQLITE_CONSTRAINT, any database changes made by ** the xUpdate method are automatically rolled back by SQLite. ** ** IMPORTANT: The estimatedRows field was added to the sqlite3_index_info ** structure for SQLite [version 3.8.2] ([dateof:3.8.2]). ** If a virtual table extension is ** used with an SQLite version earlier than 3.8.2, the results of attempting ** to read or write the estimatedRows field are undefined (but are likely ** to included crashing the application). The estimatedRows field should ** therefore only be used if [sqlite3_libversion_number()] returns a ** value greater than or equal to 3008002. Similarly, the idxFlags field ** was added for [version 3.9.0] ([dateof:3.9.0]). ** It may therefore only be used if ** sqlite3_libversion_number() returns a value greater than or equal to ** 3009000.
68691. OK to spill pager cache
68692. Expression tree height of current sub-select
68693. xShmMap method
68694. Blob handle open on %_segments table
68695. ** Step the cursor to the back to the previous entry in the database. ** Return values: ** ** SQLITE_OK success ** SQLITE_DONE the cursor is already on the first element of the table ** otherwise some kind of error occurred ** ** The main entry point is sqlite3BtreePrevious(). That routine is optimized ** for the common case of merely decrementing the cell counter BtCursor.aiIdx ** to the previous cell on the current page. The (slower) btreePrevious() ** helper routine is called when it is necessary to move to a different page ** or to restore the cursor. ** ** If bit 0x01 of the F argument to sqlite3BtreePrevious(C,F) is 1, then ** the cursor corresponds to an SQL index and this routine could have been ** skipped if the SQL index had been a unique index. The F argument is a ** hint to the implement. The native SQLite btree implementation does not ** use this hint, but COMDB2 does.
68696. Level for the new search point
68697. 98
68698. PRAGMA synchronous=FULL
68699. Buffer to write page data to

68783. Restriction (5)
68784. Authenticated as an administrator
68785. ** Create a "unicode61" tokenizer.
68786. Allocate space for the Fts3MultiSegReader.aCsr[] array

68787. Write the extra pages and truncate the database file as required
68788. ** Return true if the current thread holds the database connection ** mutex and all required BtShared mutexes. *** This routine is used inside assert() statements only.
68789. Special case - the last token of the snippet is also the last token ** of the column. Append any punctuation that occurred between the end ** of the previous token and the end of the document to the output. ** Then break out of the loop.
68790. ** CAPI3REF: Enable Or Disable Extension Loading ** METHOD: sqlite3 *** ^So as not to open security holes in older applications that are ** unprepared to deal with [extension loading], and as a means of disabling ** [extension loading] while evaluating user-entered SQL, the following API ** is provided to turn the [sqlite3_load_extension()] mechanism on and off. *** ^Extension loading is off by default. ** ^Call the sqlite3_enable_load_extension() routine with onoff==1 ** to turn extension loading on and call it with onoff==0 to turn ** it back off again. *** ^This interface enables or disables both the C-API ** [sqlite3_load_extension()] and the SQL function [load_extension()]. ** ^Use [sqlite3_db_config](db, [SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION],...) ** to enable or disable only the C-API.)^ *** Security warning: It is recommended that extension loading ** be disabled using the [SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION] method ** rather than this interface, so the [load_extension()] SQL function ** remains disabled. This will prevent SQL injections from giving attackers ** access to extension loading capabilities.
68791. ** Delete the named file. *** Note that Windows does not allow a file to be deleted if some other ** process has it open. Sometimes a virus scanner or indexing program ** will open a journal file shortly after it is created in order to do ** whatever it does. While this other process is holding the ** file open, we will be unable to delete it. To work around this ** problem, we delay 100 milliseconds and try to delete again. Up ** to MX_DELETION_ATTEMPTS deletion attempts are run before giving ** up and returning an error.
68792. ** Bind a blob value to an SQL statement variable.
68793. ** CAPI3REF: Impose A Limit On Heap Size *** ^The sqlite3_soft_heap_limit64() interface sets and/or queries the ** soft limit on the amount of heap memory that may be allocated by SQLite. ** ^SQLite strives to keep heap memory utilization below the soft heap ** limit by reducing the number of pages held in the page cache ** as heap memory usages approaches the limit. ** ^The soft heap limit is "soft" because even though SQLite strives to stay ** below the limit, it will exceed the limit rather than generate ** an [SQLITE_NOMEM] error. In other words, the soft heap limit ** is advisory only. *** ^The return value from sqlite3_soft_heap_limit64() is the size of ** the soft heap limit prior to the call, or negative in the case of an ** error. ^If the argument N is negative ** then no change is made to the soft heap limit. Hence, the current ** size of the soft heap limit can be determined by invoking ** sqlite3_soft_heap_limit64() with a negative argument. *** ^If the argument N is zero then the soft heap limit is disabled. *** ^The soft heap limit is not enforced in the current implementation ** if one or more of following conditions are true: *** ** The soft heap limit is set to zero. ** Memory accounting is disabled using a combination of the ** [sqlite3_config](SQLITE_CONFIG_MEMSTATUS,...) start-time option and ** the [SQLITE_DEFAULT_MEMSTATUS] compile-time option. ** An alternative page cache implementation is specified using ** [sqlite3_config](SQLITE_CONFIG_PCACHE2,...). ** The page cache allocates from its own memory pool supplied ** by [sqlite3_config](SQLITE_CONFIG_PAGECACHE,...) rather than ** from the heap. ** ^ *** Beginning with SQLite [version 3.7.3] ([dateof:3.7.3]), ** the soft heap limit is enforced ** regardless of whether or not the [SQLITE_ENABLE_MEMORY_MANAGEMENT] ** compile-time option is invoked. With [SQLITE_ENABLE_MEMORY_MANAGEMENT], ** the soft heap limit is enforced on every memory allocation. Without ** [SQLITE_ENABLE_MEMORY_MANAGEMENT], the soft heap limit is only enforced ** when memory is allocated by the page cache. Testing suggests that because ** the page cache is the predominate memory user in SQLite, most ** applications will achieve adequate soft heap limit enforcement without ** the use of [SQLITE_ENABLE_MEMORY_MANAGEMENT]. *** ^The circumstances under which SQLite will enforce the soft heap limit may ** changes in future releases of SQLite.
68794. UNION
68795. Prior to version 3.1.2, when LIMIT and OFFSET had to be simple constants, ** not arbitrary expressions, we allowed some combining of LIMIT and OFFSET ** because they could be computed at compile-time. But when LIMIT and OFFSET ** became arbitrary expressions, we were forced to add restrictions (13) ** and (14).
68796. ** Constant tokens for values 0 and 1.
68797. ***** Begin Unique File ID Utility Used By VxWorks ***** On most versions of unix, we can get a unique ID for a file by concatenating ** the device number and the inode number. But this does not work on VxWorks. ** On VxWorks, a unique file id must be based on the canonical filename. *** ^A pointer to an instance of the following structure can be used as a ** unique file ID in VxWorks. Each instance of this structure contains ** a copy of the canonical filename. There is also a reference count. ** The structure is reclaimed when the number of pointers to it drops to ** zero. *** ^There are never very many files open at one time and lookups are not ** a performance-critical path, so it is sufficient to put these ** structures on a linked list.
68798. Miscellaneous flags. See below
68799. String pointer
68800. SQLITE_OMIT_SUBQUERY
68801. only re-establish the shared lock if necessary
68802. ** Attempt to reallocate p. If the reallocation fails, then free p ** and set the mallocFailed flag in the database connection.
68803. phrase
68804. Size of scratch memory requested
68805. ** Maximum depth of an SQLite B-Tree structure. Any B-Tree deeper than ** this will be declared corrupt. This value is calculated based on a ** maximum database size of 2^31 pages a minimum fanout of 2 for a ** root-node and 3 for all other internal nodes. *** ^If a tree that appears to be taller than this is encountered, it is ** assumed that the database is corrupt.
68806. ** If FTS_LOG_MERGES is defined, call sqlite3_log() to report each automatic ** and incremental merge operation that takes place. This is used for ** debugging FTS only, it should not usually be turned on in production ** systems.
68807. End non-truncate path

68887. The number of == or IN constraints to code

68888. Size of term suffix

68889. Allocate a new page. This page will become the right-sibling of ** pPage. Make the parent page writable, so that the new divider cell ** may be inserted. If both these operations are successful, proceed.

68890. rc==0 here means that one or both of the keys ran out of fields and ** all the fields up to that point were equal. Return the default_rc ** value.

68891. Increment the xRowid value

68892. Index of the database to use

68893. ** Interpret the argument as a unicode codepoint. If the codepoint ** is an upper case character that has a lower case equivalent, ** return the codepoint corresponding to the lower case version. ** Otherwise, return a copy of the argument. ** ** The results are undefined if the value passed to this function ** is less than zero.

68894. Also used in P2 (not P5) of OP_Delete

68895. **comment:** ** Parameter zMaster is the name of a master journal file. A single journal ** file that referred to the master journal file has just been rolled back. ** This routine checks if it is possible to delete the master journal file, ** and does so if it is. ** ** Argument zMaster may point to Pager.pTmpSpace. So that buffer is not ** available for use within this function. ** ** When a master journal file is created, it is populated with the names ** of all of its child journals, one after another, formatted as utf-8 ** encoded text. The end of each child journal file is marked with a ** nul-terminator byte (0x00). i.e. the entire contents of a master journal ** file for a transaction involving two databases might be: ** ** "/home/bill/a.db-journal\x00/home/bill/b.db-journal\x00" ** ** A master journal file may

only be deleted once all of its child ** journals have been rolled back. *** This function reads the contents of the master-journal file into ** memory and loops through each of the child journal names. For ** each child journal, it checks if: *** * if the child journal exists, and if so ** * if the child journal contains a reference to master journal ** file zMaster *** If a child journal can be found that matches both of the criteria ** above, this function returns without doing anything. Otherwise, if ** no such child journal can be found, file zMaster is deleted from ** the file-system using sqlite3OsDelete(). *** If an IO error within this function, an error code is returned. This ** function allocates memory by calling sqlite3Malloc(). If an allocation ** fails, SQLITE_NOMEM is returned. Otherwise, if no IO or malloc errors ** occur, SQLITE_OK is returned. *** TODO: This function allocates a single block of memory to load ** the entire contents of the master journal file. This could be ** a couple of kilobytes or so - potentially larger than the page ** size.

68991. ** CAPI3REF: Database Connection Configuration Options ** ** These constants are the available integer configuration options that ** can be passed as the second argument to the [sqlite3_db_config()] interface. ** ** New configuration options may be added in future releases of SQLite. ** Existing configuration options might be discontinued. Applications ** should check the return code from [sqlite3_db_config()] to make sure that ** the call worked. ^The [sqlite3_db_config()] interface will return a ** non-zero [error code] if a discontinued or unsupported configuration option ** is invoked. ** ** <dd> ** <dt>SQLITE_DBCONFIG_LOOKASIDE</dt> ** <dd> ^This option takes three additional arguments that determine the ** [lookaside memory allocator] configuration for the [database connection]. ** ^The first argument (the third parameter to [sqlite3_db_config()]) is a ** pointer to a memory buffer to use for lookaside memory. ** ^The first argument after the SQLITE_DBCONFIG_LOOKASIDE verb ** may be NULL in which case SQLite will allocate the ** lookaside buffer itself using [sqlite3_malloc()]. ^The second argument is the ** size of each lookaside buffer slot. ^The third argument is the number of ** slots. The size of the buffer in the first argument must be greater than ** or equal to the product of the second and third arguments. The buffer ** must be aligned to an 8-byte boundary. ^If the second argument to ** SQLITE_DBCONFIG_LOOKASIDE is not a multiple of 8, it is internally ** rounded down to the next smaller multiple of 8. ^The lookaside memory ** configuration for a database connection can only be changed when that ** connection is not currently using lookaside memory, or in other words ** when the "current value" returned by ** [sqlite3_db_status](D,[SQLITE_CONFIG_LOOKASIDE],..) is zero. ** Any attempt to change the lookaside memory configuration when lookaside ** memory is in use leaves the configuration unchanged and returns ** [SQLITE_BUSY].^</dd> ** <dt>SQLITE_DBCONFIG_ENABLE_FKEY</dt> ** <dd> ^This option is used to enable or disable the enforcement of ** [foreign key constraints]. There should be two additional arguments. ** The first argument is an integer which is 0 to disable FK enforcement, ** positive to enable FK enforcement or negative to leave FK enforcement ** unchanged. The second parameter is a pointer to an integer into which ** is written 0 or 1 to indicate whether FK enforcement is off or on ** following this call. The second parameter may be a NULL pointer, in ** which case the FK enforcement setting is not reported back. </dd> ** ** <dt>SQLITE_DBCONFIG_ENABLE_TRIGGER</dt> ** <dd> ^This option is used to enable or disable [CREATE TRIGGER | triggers]. ** There should be two additional arguments. ** The first argument is an integer which is 0 to disable triggers, ** positive to enable triggers or negative to leave the setting unchanged. ** The second parameter is a pointer to an integer into which ** is written 0 or 1 to indicate whether triggers are disabled or enabled ** following this call. The second parameter may be a NULL pointer, in ** which case the trigger setting is not reported back. </dd> ** ** <dt>SQLITE_DBCONFIG_ENABLE_FTS3_TOKENIZER</dt> ** <dd> ^This option is used to enable or disable the two-argument ** version of the [fts3_tokenizer()] function which is part of the ** [FTS3] full-text search engine extension. ** There should be two additional arguments. ** The first argument is an integer which is 0 to disable fts3_tokenizer() or ** positive to enable fts3_tokenizer() or negative to leave the setting ** unchanged. ** The second parameter is a pointer to an integer into which ** is written 0 or 1 to indicate whether fts3_tokenizer is disabled or enabled ** following this call. The second parameter may be a NULL pointer, in ** which case the new setting is not reported back. </dd> ** ** <dt>SQLITE_DBCONFIG_ENABLE_LOAD_EXTENSION</dt> ** <dd> ^This option is used to enable or disable the [sqlite3_load_extension()] ** interface independently of the [load_extension()] SQL function. ** The [sqlite3_enable_load_extension()] API enables or disables both the ** C-API [sqlite3_load_extension()] and the SQL function [load_extension()]. ** There should be two additional arguments. ** When the first argument to this interface is 1, then only the C-API is ** enabled and the SQL function remains disabled. If the first argument to ** this interface is 0, then both the C-API and the SQL function are disabled. ** If the first argument is -1, then no changes are made to state of either the ** C-API or the SQL function. ** The second parameter is a pointer to an integer into which ** is written 0 or 1 to indicate whether [sqlite3_load_extension()] interface ** is disabled or enabled following this call. The second parameter may ** be a NULL pointer, in which case the new setting is not reported back. ** </dd> ** ** <dt>SQLITE_DBCONFIG_MAINDBNAME</dt> ** <dd> ^This option is used to change the name of the "main" database ** schema. ^The sole argument is a pointer to a constant UTF8 string ** which will become the new schema name in place of "main". ^SQLite ** does not make a copy of the new main schema name string, so the application ** must ensure that the argument passed into this DBCONFIG option is unchanged ** until after the database connection closes. ** </dd> ** ** <dt>SQLITE_DBCONFIG_NO_CKPT_ON_CLOSE</dt> ** <dd> Usually, when a database in wal mode is closed or detached from a ** database handle, SQLite checks if this will mean that there are now no ** connections at all to the database. If so, it performs a checkpoint ** operation before closing the connection. This option may be used to ** override this behaviour. The first parameter passed to this operation ** is an integer - non-zero to disable checkpoints-on-close, or zero (the ** default) to enable them. The second parameter is a pointer to an integer ** into which is written 0 or 1 to indicate whether checkpoints-on-close ** have been disabled - 0 if they are not disabled, 1 if they are. ** </dd> ** ** <dt>SQLITE_DBCONFIG_ENABLE_QPSG</dt> ** <dd> ^The SQLITE_DBCONFIG_ENABLE_QPSG option activates or deactivates ** the [query planner stability guarantee] (QPSG). When the QPSG is active, ** a single SQL query statement will always use the same algorithm regardless ** of values of [bound parameters].^< The QPSG disables some query optimizations ** that look at the values of bound parameters, which can make some queries ** slower. But the QPSG has the advantage of more predictable behavior. With ** the QPSG active, SQLite will always use the same query plan in the field as ** was used during testing in the lab. ** </dd> ** ** </dl>

68992. ***** End of btmutex.c *****

68993. ** This function is used to change the actual size of the database ** file in the file-system. This only happens when committing a transaction, ** or rolling back a transaction (including rolling back a hot-journal). *** If the main database file is not open, or the pager is not in either ** DBMOD or OPEN state, this function is a no-op. Otherwise, the size ** of the file is changed to nPage pages (nPage*pPager->pageSize bytes). ** If the file on disk is currently larger than nPage pages, then use the VFS ** xTruncate() method to truncate it. *** Or, it might be the case that the file on disk is smaller than ** nPage pages. Some operating system implementations can get confused if ** you try to truncate a file to some size that is larger than it ** currently is, so detect this case and write a single zero byte to ** the end of the new file instead. *** If successful, return SQLITE_OK. If an IO error occurs while modifying ** the database file, return the error code to the caller.

68994. Mask of new.* columns referenced

68995. NodeWriter for root node

68996. The DISTINCT marking is pointless. Ignore it.

68997. CREATE VIEW name(arglist) AS ... ** The names of the columns in the table are taken from ** arglist which is stored in pTable->pCheck. The pCheck field ** normally holds CHECK constraints on an ordinary table, but for ** a VIEW it holds the list of column names.

68998. Cache of overflow page locations

68999. OUT: Size of buffer at *ppChangese

69000. ** CAPI3REF: Create A New Changegroup Object ** ** An sqlite3_changegroup object is used to combine two or more changesets ** (or patchsets) into a single changeset (or patchset). A single changegroup ** object may combine changesets or patchsets, but not both. The output is ** always in the same format as the input. ** ** If successful, this function returns SQLITE_OK and populates (*pp) with ** a pointer to a new sqlite3_changegroup object before returning. The caller ** should eventually free the returned object using a call to ** sqlite3changegroup_delete(). If an error occurs, an SQLite error code ** (i.e. SQLITE_NOMEM) is returned and *pp is set to NULL. ** ** The usual usage pattern for an sqlite3_changegroup object is as follows: ** ** ** It is created using a call to sqlite3changegroup_new(). ** ** Zero or more changesets (or patchsets) are added to the object ** by calling sqlite3changegroup_add(). ** ** The result of combining all input changesets together is obtained ** by the application via a call to sqlite3changegroup_output(). ** ** The object is deleted using a call to sqlite3changegroup_delete(). ** ** ** Any number of calls to add() and output() may be made between the calls to ** new() and delete(), and in any order. ** ** As well as the regular sqlite3changegroup_add() and ** sqlite3changegroup_output() functions, also available are the streaming ** versions sqlite3changegroup_add_strm() and sqlite3changegroup_output_strm().

69001. A WHERE clause term

69002. ** Candidate values for Wal.exclusiveMode.

69051. Access authorization function
69052. Find a dirty page to write-out and recycle. First try to find a ** page that does not require a journal-sync (one with PGHDR_NEED_SYNC ** cleared), but if that is not possible settle for any other ** unreferenced dirty page. ** ** If the LRU page in the dirty list that has a clear PGHDR_NEED_SYNC ** flag is currently referenced, then the following may leave pSynced ** set incorrectly (pointing to other than the LRU page with NEED_SYNC ** cleared). This is Ok, as pSynced is just an optimization.
69053. BY => ID
69054. ** This is an fts3ExprIterate() callback used while loading the doclists ** for each phrase into Fts3Expr.aDoclist[]/nDoclist. See also ** fts3ExprLoadDoclists().
69055. Collating sequence name
69056. Dummy variables
69057. Step 1C.
69058. Byte available in aRow
69059. IMPLEMENTATION-OF: R-59782-36818 The SQLITE_CHECKPOINT_FULL, RESTART and ** TRUNCATE modes also obtain the exclusive "writer" lock on the database ** file. ** ** EVIDENCE-OF: R-60642-04082 If the writer lock cannot be obtained ** immediately, and a busy-handler is configured, it is invoked and the ** writer lock retried until either the busy-handler returns 0 or the ** lock is successfully obtained.
69060. ** Delete the file located at zPath.
69061. The underlying file iNode
69062. Current offset in pgidx
69063. pIdx is usable
69064. In the IEEE 754 standard, zero is signed.
69065. The following testcase is true for indices with redundant columns. ** Ex: CREATE INDEX i1 ON t1(a,b,a); SELECT * FROM t1 WHERE a=0 AND b=0;
69066. SQLITE_OMIT_TRACE
69067. List of statements inside the trigger body
69068. Rowid from %_data table
69069. Destructor for pUserData
69070. ** This function returns a pointer to a blob of memory associated with ** a single shared-btree. The memory is used by client code for its own ** purposes (for example, to store a high-level schema associated with ** the shared-btree). The btree layer manages reference counting issues. ** ** The first time this is called on a shared-btree, nBytes bytes of memory ** are allocated, zeroed, and returned to the caller. For each subsequent ** call the nBytes parameter is ignored and a pointer to the same blob ** of memory returned. ** ** If the nBytes parameter is 0 and the blob of memory has not yet been ** allocated, a null pointer is returned. If the blob has already been ** allocated, it is returned as normal. ** ** Just before the shared-btree is closed, the function passed as the ** xFree argument when the memory allocation was made is invoked on the ** blob of allocated memory. The xFree function should not call sqlite3_free() ** on the memory, the btree layer does that.
69071. Make sure the results of the current row are \000 terminated ** and have an assigned type. The results are de-ephemeralized as ** a side effect.
69072. If we have any lock, then the lock file already exists. All we have ** to do is adjust our internal record of the lock level.
69073. colset
69074. ** This routine is called when a VDBE tries to halt. If the VDBE ** has made changes and is in autocommit mode, then commit those ** changes. If a rollback is needed, then do the rollback. ** ** This routine is the only way to move the state of a VM from ** SQLITE_MAGIC_RUN to SQLITE_MAGIC_HALT. It is harmless to ** call this on a VM that is in the SQLITE_MAGIC_HALT state. ** ** Return an error code. If the commit could not complete because of ** lock contention, return SQLITE_BUSY. If SQLITE_BUSY is returned, it ** means the close did not happen and needs to be repeated.
69075. True for ORDER BY ASC
69076. Rare case of a really large header
69077. 240
69078. Try to allocate nByte bytes of 8-byte aligned bulk memory for pBuf ** from the ReusableSpace object. Return a pointer to the allocated ** memory on success. If insufficient memory is available in the ** ReusableSpace object, increase the ReusableSpace.nNeeded ** value by the amount needed and return NULL. ** ** If pBuf is not initially NULL, that means that the memory has already ** been allocated by a prior call to this routine, so just return a copy ** of pBuf and leave ReusableSpace unchanged. ** ** This allocator is employed to repurpose unused slots at the end of the ** opcode array of prepared state for other memory needs of the prepared ** statement.
69079. If this index contains every column of its table, then mark ** it as a covering index
69080. ** Used to pass information from the analyzer reader through to the ** callback routine.
69081. Register to copy to
69082. ** Return true if the correct mutexes are held for accessing the ** db->aDb[iDb].pSchema structure. The mutexes required for schema ** access are: ** ** (1) The mutex on db ** (2) if iDb!=1, then the mutex on db->aDb[iDb].pBt. ** ** If pSchema is not NULL, then iDb is computed from pSchema and ** db using sqlite3SchemaToIndex().
69083. Remove result from a UNION index
69084. ** If we are on an architecture with mixed-endian floating ** points (ex: ARM7) then swap the lower 4 bytes with the ** upper 4 bytes. Return the result. ** ** For most architectures, this is a no-op. ** ** (later): It is reported to me that the mixed-endian problem ** on ARM7 is an issue with GCC, not with the ARM7 chip. It seems ** that early versions of GCC stored the two words of a 64-bit ** float in the wrong order. And that error has been propagated ** ever since. The blame is not necessarily with GCC, though. ** GCC might have just copying the problem from a prior compiler. ** I am also told that newer versions of GCC that follow a different ** ABI get the byte order right. ** ** Developers using SQLite on an ARM7 should compile and run their ** application using -DSQLITE_DEBUG=1 at least once. With DEBUG ** enabled, some asserts below will ensure that the byte order of ** floating point values is correct. ** ** (2007-08-30) Frank van Vugt has studied this problem closely ** and has sent his findings to the SQLite developers. Frank ** writes that some Linux kernels offer floating point hardware ** emulation that uses only 32-bit mantissas instead of a full ** 48-bits as required by the IEEE standard. (This is the ** CONFIG_FPE_FASTFP option.) On such systems, floating point ** byte swapping becomes very complicated. To avoid problems, ** the necessary byte swapping is carried out using a 64-bit integer ** rather than a 64-bit float. Frank assures us that the code here ** works for him. We, the developers, have no way to independently ** verify this, but Frank seems to know what he is talking about ** so we trust him.
69085. If an OOM occurs, set to SQLITE_NOMEM
69086. Reserved: 0x00F00000
69087. Never set both isSaveLeft and isExact for the same invocation.
69088. The next sections is a series of control #defines. ** various aspects of the generated parser. ** fts5YYCODETYPE is the data type used to store the integer codes ** that represent terminal and non-terminal symbols. ** "unsigned char" is used if there are fewer than ** 256 symbols. Larger types otherwise. ** fts5YYNOCODE is a number of type fts5YYCODETYPE that is not used for ** any terminal or nonterminal symbol. ** fts5YYFALLBACK If defined, this indicates that one or more tokens ** (also known as: "terminal symbols") have fall-back ** values which should be used if the original symbol ** would not parse.

This permits keywords to sometimes ** be used as identifiers, for example. ** fts5YYACTIONTYPE is the data type used for "action codes" - numbers ** that indicate what to do in response to the next ** token. ** sqlite3Fts5ParserFTS5TOKENTYPE is the data type used for minor type for terminal ** symbols. Background: A "minor type" is a semantic ** value associated with a terminal or non-terminal ** symbols. For example, for an "ID" terminal symbol, ** the minor type might be the name of the identifier. ** Each non-terminal can have a different minor type. ** Terminal symbols all have the same minor type, though. ** This macros defines the minor type for terminal ** symbols. ** fts5YYMINORTYPE is the data type used for all minor types. ** This is typically a union of many types, one of ** which is sqlite3Fts5ParserFTS5TOKENTYPE. The entry in the union ** for terminal symbols is called "fts5yy0". ** fts5YYSTACKDEPTH is the maximum depth of the parser's stack. If ** zero the stack is dynamically sized using realloc() ** sqlite3Fts5ParserARG_SDECL A static variable declaration for the %extra_argument ** sqlite3Fts5ParserARG_PDECL A parameter declaration for the %extra_argument ** sqlite3Fts5ParserARG_STORE Code to store %extra_argument into fts5yypParser ** sqlite3Fts5ParserARG_FETCH Code to extract %extra_argument from fts5yypParser ** fts5YYERRORSYMBOL is the code number of the error symbol. If not ** defined, then do no error processing. ** fts5YYNSTATE the combined number of states. ** fts5YYNRULE the number of rules in the grammar ** fts5YY_MAX_SHIFT Maximum value for shift actions ** fts5YY_MIN_SHIFTREDUCE Minimum value for shift-reduce actions ** fts5YY_MAX_SHIFTREDUCE Maximum value for shift-reduce actions ** fts5YY_MIN_REDUCE Maximum value for reduce actions ** fts5YY_ERROR_ACTION The fts5yy_action[] code for syntax error ** fts5YY_ACCEPT_ACTION The fts5yy_action[] code for accept ** fts5YY_NO_ACTION The fts5yy_action[] code for no-op

69089. Maximum local payload in a LEAFDATA table

69090. Free-list trunk page

69091. ** Attach a table to a session. All subsequent changes made to the table ** while the session object is enabled will be recorded. ** ** Only tables that have a PRIMARY KEY defined may be attached. It does ** not matter if the PRIMARY KEY is an "INTEGER PRIMARY KEY" (rowid alias) ** or not.

69092. Symbolic ID of this loop for debugging use

69093. **comment:** ** The "winIoerrCanRetry1" macro is used to determine if a particular I/O ** error code obtained via GetLastError() is eligible to be retried. It ** must accept the error code DWORD as its only argument and should return ** non-zero if the error code is transient in nature and the operation ** responsible for generating the original error might succeed upon being ** retried. The argument to this macro should be a variable. ** ** Additionally, a macro named "winIoerrCanRetry2" may be defined. If it ** is defined, it will be consulted only when the macro "winIoerrCanRetry1" ** returns zero. The "winIoerrCanRetry2" macro is completely optional and ** may be used to include additional error codes in the set that should ** result in the failing I/O operation being retried by the caller. If ** defined, the "winIoerrCanRetry2" macro must exhibit external semantics ** identical to those of the "winIoerrCanRetry1" macro.

69436. ** CAPI3REF: The pre-update hook. ** ** ^These interfaces are only available if SQLite is compiled using the ** [SQLITE_ENABLE_PREUPDATE_HOOK] compile-time option. ** ** ^The [sqlite3_preupdate_hook()] interface registers a callback function ** that is invoked prior to each [INSERT], [UPDATE], and [DELETE] operation ** on a database table. ** ^At most one preupdate hook may be registered at a time on a single ** [database connection]; each call to [sqlite3_preupdate_hook()] overrides ** the previous setting. ** ^The preupdate hook is disabled by invoking [sqlite3_preupdate_hook()] ** with a NULL pointer as the second parameter. ** ^The third parameter to [sqlite3_preupdate_hook()] is passed through as ** the first parameter to callbacks. ** ** ^The preupdate hook only fires for changes to real database tables; the ** preupdate hook is not invoked for changes to [virtual tables] or to ** system tables like sqlite_master or sqlite_stat1. ** ** ^The second parameter to the preupdate callback is a pointer to ** the [database connection] that registered the preupdate hook. ** ^The third parameter to the preupdate callback is one of the constants ** [SQLITE_INSERT], [SQLITE_DELETE], or [SQLITE_UPDATE] to identify the ** kind of update operation that is about to occur. ** ^The fourth parameter to the preupdate callback is the name of the ** database within the database connection that is being modified. This ** will be "main" for the main database or "temp" for TEMP tables or ** the name given after the AS keyword in the [ATTACH] statement for attached ** databases.)^ ** ^The fifth parameter to the preupdate callback is the name of the ** table that is being modified. ** ** For an UPDATE or DELETE operation on a [rowid table], the sixth ** parameter passed to the preupdate callback is the initial [rowid] of the ** row being modified or deleted. For an INSERT operation on a rowid table, ** or any operation on a WITHOUT ROWID table, the value of the sixth ** parameter is undefined. For an INSERT or UPDATE on a rowid table the ** seventh parameter is the final rowid value of the row being inserted ** or updated. The value of the seventh parameter passed to the callback ** function is not defined for operations on WITHOUT ROWID tables, or for ** INSERT operations on rowid tables. ** ** The [sqlite3_preupdate_old()], [sqlite3_preupdate_new()], [sqlite3_preupdate_count()], and [sqlite3_preupdate_depth()] interfaces ** provide additional information about a preupdate event. These routines ** may only be called from within a preupdate callback. Invoking any of ** these routines from outside of a preupdate callback or with a ** [database connection] pointer that is different from the one supplied ** to the preupdate callback results in undefined and probably undesirable ** behavior. ** ** ^The [sqlite3_preupdate_count(D)] interface returns the number of columns ** in the row that is being inserted, updated, or deleted. ** ** ^The [sqlite3_preupdate_old(D,N,P)] interface writes into P a pointer to ** a [protected sqlite3_value] that contains the value of the Nth column of ** the table row before it is updated. The N parameter must be between 0 ** and one less than the number of columns or the behavior will be ** undefined. This must only be used within SQLITE_UPDATE and SQLITE_DELETE ** preupdate callbacks; if it is used by an SQLITE_INSERT callback then the ** behavior is undefined. The [sqlite3_value] that P points to ** will be destroyed when the preupdate callback returns. ** ** ^The [sqlite3_preupdate_new(D,N,P)] interface writes into P a pointer to ** a [protected sqlite3_value] that contains the value of the Nth column of ** the table row after it is updated. The N parameter must be between 0 ** and one less than the number of columns or the behavior will be ** undefined. This must only be used within SQLITE_INSERT and SQLITE_UPDATE ** preupdate callbacks; if it is used by an SQLITE_DELETE callback then the ** behavior is undefined. The [sqlite3_value] that P points to ** will be destroyed when the preupdate callback returns. ** ** ^The [sqlite3_preupdate_depth(D)] interface returns 0 if the preupdate ** callback was invoked as a result of a direct insert, update, or delete ** operation; or 1 for inserts, updates, or deletes invoked by top-level ** triggers; or 2 for changes resulting from triggers called by top-level ** triggers; and so forth. ** ** See also: [sqlite3_update_hook()]

69437. The first page of the wal-index must be mapped at this point.

69438. Copy entry from i2

69439. ** Initialize a WHERE clause scanner object. Return a pointer to the ** first match. Return NULL if there are no matches. ** ** The scanner will be searching the WHERE clause pWC. It will look ** for terms of the form "X <op> <expr>" where X is column iColumn of table ** iCur. Or if pIdx!=0 then X is column iColumn of index pIdx. pIdx ** must be one of the indexes of table iCur. ** ** The <op> must be one of the operators described by opMask. ** ** If the search is for X and the WHERE clause contains terms of the ** form X=Y then this routine might also return terms of the form ** "Y <op> <expr>". The number of levels of transitivity is limited, ** but is enough to handle most commonly occurring SQL statements. ** ** If X is not the INTEGER PRIMARY KEY then X must be compatible with ** index pIdx.

69440. ** This function is called as part of sqlite3rbu_open() when initializing ** an rbu handle in OAL stage. If the rbu update has not started (i.e. ** the rbu_state table was empty) it is a no-op. Otherwise, it arranges ** things so that the next call to sqlite3rbu_step() continues on from ** where the previous rbu handle left off. ** ** If an error occurs, an error code and error message are left in the ** rbu handle passed as the first argument.

69441. IN/OUT: Number of elements in aList[]

69442. Bytes of space to allocate for this node

69443. Pointer to the root node of a tree

69444. The database file to check

69445. The key for INTKEY tables, or nPayload otherwise

69446. Parsing context

69447. ** The code above is the AFP lock implementation. The code is specific ** to MacOSX and does not work on other unix platforms. No alternative ** is available. If you don't compile for a mac, then the "unix-afp" ** VFS is not available. ** ***** End of the AFP lock implementation *****

69448. Merge PMAs together

** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This file contains the C functions that implement a memory **
allocation subsystem for use by SQLite. *** This version of the memory allocation subsystem omits all ** use of malloc(). The application gives SQLite a block of memory ** before calling sqlite3_initialize() from which allocations ** are made and returned by the xMalloc() and xRealloc() ** implementations. Once sqlite3_initialize() has been called, ** the amount of memory available to SQLite is fixed and cannot ** be changed. *** This version of the memory allocation subsystem is included ** in the build only if SQLITE_ENABLE_MEMSYS5 is defined. *** This memory allocator uses the following algorithm: *** 1. All memory allocation sizes are rounded up to a power of 2. *** 2. If two adjacent free blocks are the halves of a larger block, ** then the two blocks are coalesced into the single larger block. *** 3. New memory is allocated from the first available free block. *** This algorithm is described in: J. M. Robson. "Bounds for Some Functions ** Concerning Dynamic Storage Allocation". Journal of the Association for ** Computing Machinery, Volume 21, Number 8, July 1974, pages 491-499. *** Let n be the size of the largest allocation divided by the minimum ** allocation size (after rounding all sizes up to a power of 2.) Let M ** be the maximum amount of memory ever outstanding at one time. Let ** N be the total amount of memory available for allocation. Robson ** proved that this memory allocator will never breakdown due to ** fragmentation as long as the following constraint holds: *** N >= M*(1 + log2(n)/2) - n + 1 *** The sqlite3_status() logic tracks the maximum values of n and M so ** that an application can, at any time, verify this constraint.
69496. FROM clause cannot contain a subquery
69497. **comment:** ** CAPI3REF: Formatted String Printing Functions *** These routines are work-alikes of the "printf()" family of functions ** from the standard C library. ** These routines understand most of the common K&R formatting options, ** plus some additional non-standard formats, detailed below. ** Note that some of the more obscure formatting options from recent ** C-library standards are omitted from this implementation. *** ^The sqlite3_mprintf() and sqlite3_vmpprintf() routines write their ** results into memory obtained from [sqlite3_malloc()]. ** The strings returned by these two routines should be ** released by [sqlite3_free()]. ^Both routines return a ** NULL pointer if [sqlite3_malloc()] is unable to allocate enough ** memory to hold the resulting string. **
*** ^The sqlite3_snprintf() routine is similar to "snprintf()" from ** the standard C library. The result is written into the ** buffer supplied as the second parameter whose size is given by ** the first parameter. Note that the order of the ** first two parameters is reversed from sprintf().^ This is an ** historical accident that cannot be fixed without breaking ** backwards compatibility. ^Note also that sqlite3_snprintf() ** returns a pointer to its buffer instead of the number of ** characters actually written into the buffer.^ We admit that ** the number of characters written would be a more useful return ** value but we cannot change the implementation of sqlite3_snprintf() ** now without breaking compatibility. *** ^As long as the buffer size is greater than zero, sqlite3_snprintf() ** guarantees that the buffer is always zero-terminated. ^The first ** parameter "n" is the total size of the buffer, including space for ** the zero terminator. So the longest string that can be completely ** written will be n-1 characters. *** ^The sqlite3_vsnprintf() routine is a varargs version of sqlite3_snprintf(). *** These routines all implement some additional formatting ** options that are useful for constructing SQL statements. ** All of the usual printf() formatting options apply. In addition, there ** is are "%q", "%Q", "%w" and "%z" options. *** ^The %q option works like %s in that it substitutes a null-terminated ** string from the argument list. But %q also doubles every \" character. ** %q is designed for use inside a string literal.^ By doubling each \" ** character it escapes that character and allows it to be inserted into ** the string. *** For example, assume the string variable zText contains text as follows: *** <blockquote><pre> ** char *zText = "It's a happy day!"; ** </pre></blockquote> *** One can use this text in an SQL statement as follows: *** <blockquote><pre> ** char *zSQL = sqlite3_mprintf("INSERT INTO table VALUES(%q)", zText); ** sqlite3_exec(db, zSQL, 0, 0, 0); ** sqlite3_free(zSQL); ** </pre></blockquote> *** Because the %q format string is used, the \" character in zText ** is escaped and the SQL generated is as follows: *** <blockquote><pre> ** INSERT INTO table1 VALUES('It's a happy day!') ** </pre></blockquote> *** This is correct. Had we used %s instead of %q, the generated SQL ** would have looked like this: *** <blockquote><pre> ** INSERT INTO table1 VALUES(It's a happy day!); ** </pre></blockquote> *** This second example is an SQL syntax error. As a general rule you should ** always use %q instead of %s when inserting text into a string literal. *** ^The %Q option works like %q except it also adds single quotes around ** the outside of the total string. Additionally, if the parameter in the ** argument list is a NULL pointer, %Q substitutes the text "NULL" (without ** single quotes).^ So, for example, one could say: *** <blockquote><pre> ** char *zSQL = sqlite3_mprintf("INSERT INTO table VALUES(%Q)", zText); ** sqlite3_exec(db, zSQL, 0, 0, 0); ** sqlite3_free(zSQL); ** </pre></blockquote> *** The code above will render a correct SQL statement in the zSQL ** variable even if the zText variable is a NULL pointer. *** ^The "%w" formatting option is like "%q" except that it expects to ** be contained within double-quotes instead of single quotes, and it ** escapes the double-quote character instead of the single-quote ** character.^ The "%w" formatting option is intended for safely inserting ** table and column names into a constructed SQL statement. *** ^The "%z" formatting option works like "%s" but with the ** addition that after the string has been read and copied into ** the result, [sqlite3_free()] is called on the input string.^

69541. Do a binary search to find the first sample greater than or equal ** to pRec. If pRec contains a single field, the set of samples to search ** is simply the aSample[] array. If the samples in aSample[] contain more ** than one fields, all fields following the first are ignored. ** ** If pRec contains N fields, where N is more than one, then as well as the ** samples in aSample[] (truncated to N fields), the search also has to ** consider prefixes of those samples. For example, if the set of samples ** in aSample is: ** ** aSample[0] = (a, 5) ** aSample[1] = (a, 10) ** aSample[2] = (b, 5) ** aSample[3] = (c, 100) ** aSample[4] = (c, 105) ** ** Then the search space should ideally be the samples above and the ** unique prefixes [a], [b] and [c]. But since that is hard to organize, ** the code actually searches this set: ** ** 0: (a) ** 1: (a, 5) ** 2: (a, 10) ** 3: (a, 10) ** 4: (b) ** 5: (b, 5) ** 6: (c) ** 7: (c, 100) ** 8: (c, 105) ** 9: (c, 105) ** ** For each sample in the aSample[] array, N samples are present in the ** effective sample array. In the above, samples 0 and 1 are based on ** sample aSample[0]. Samples 2 and 3 on aSample[1] etc. ** ** Often, sample i of each block of N effective samples has (i+1) fields. ** Except, each sample may be extended to ensure that it is greater than or ** equal to the previous sample in the array. For example, in the above, ** sample 2 is the first sample of a block of N samples, so at first it ** appears that it should be 1 field in size. However, that would make it ** smaller than sample 1, so the binary search would not work. As a result, ** it is extended to two fields. The duplicates that this creates do not ** cause any problems.

69692. Only flags that can be set are SAVEPOISSION and AUXDELETE

69693. **comment:** The following describes the implementation of the various locks and ** lock transitions in terms of the POSIX advisory shared and exclusive ** lock primitives (called read-locks and write-locks below, to avoid ** confusion with SQLite lock names). The algorithms are complicated ** slightly in order to be compatible with Windows95 systems simultaneously ** accessing the same database file, in case that is ever required. *** Symbols defined in os.h indentify the 'pending byte' and the 'reserved ** byte', each single bytes at well known offsets, and the 'shared byte ** range', a range of 510 bytes at a well known offset. *** To obtain a SHARED lock, a read-lock is obtained on the 'pending ** byte'. If this is successful, 'shared byte range' is read-locked ** and the lock on the 'pending byte' released. (Legacy note: When ** SQLite was first developed, Windows95 systems were still very common, ** and Widnows95 lacks a shared-lock capability. So on Windows95, a ** single randomly selected by from the 'shared byte range' is locked. ** Windows95 is now pretty much extinct, but this work-around for the ** lack of shared-locks on Windows95 lives on, for backwards ** compatibility.) *** A process may only obtain a RESERVED lock after it has a SHARED lock. ** A RESERVED lock is implemented by grabbing a write-lock on the ** 'reserved byte'. *** A process may only obtain a PENDING lock after it has obtained a ** SHARED lock. A PENDING lock is implemented by obtaining a write-lock ** on the 'pending byte'. This ensures that no new SHARED locks can be ** obtained, but existing SHARED locks are allowed to persist. A process ** does not have to obtain a RESERVED lock on the way to a PENDING lock. ** This property is used by the algorithm for rolling back a journal file ** after a crash. *** An EXCLUSIVE lock, obtained after a PENDING lock is held, is ** implemented by obtaining a write-lock on the entire 'shared byte ** range'. Since all other locks require a read-lock on one of the bytes ** within this range, this ensures that no other locks are held on the ** database.

69740. **comment:** ***** CUSTOM TOKENIZERS *** Applications may also register custom tokenizer types. A tokenizer ** is registered by providing fts5 with a populated instance of the ** following structure. All structure methods must be defined, setting ** any member of the fts5_tokenizer struct to NULL leads to undefined ** behaviour. The structure methods are expected to function as follows: *** xCreate: ** This function is used to allocate and initialize a tokenizer instance. ** A tokenizer instance is required to actually tokenize text. *** The first argument passed to this function is a copy of the (void*) ** pointer provided by the application when the fts5_tokenizer object ** was registered with FTS5 (the third argument to xCreateTokenizer()). ** The second and third arguments are an array of nul-terminated strings ** containing the tokenizer arguments, if any, specified following the ** tokenizer name as part of the CREATE VIRTUAL TABLE statement used ** to create the FTS5 table. *** The final argument is an output variable. If successful, (*ppOut) ** should be set to point to the new tokenizer handle and SQLITE_OK ** returned. If an error occurs, some value other than SQLITE_OK should ** be returned. In this case, fts5 assumes that the final value of *ppOut ** is undefined. *** xDelete: ** This function is invoked to delete a tokenizer handle previously ** allocated using xCreate(). Fts5 guarantees that this function will ** be invoked exactly once for each successful call to xCreate(). *** xTokenize: ** This function is expected to tokenize the nText byte string indicated ** by argument pText. pText may or may not be null-terminated. The first ** argument passed to this function is a pointer to an Fts5Tokenizer object ** returned by an earlier call to xCreate(). *** The second argument indicates the reason that FTS5 is requesting ** tokenization of the supplied text. This is always one of the following ** four values: *** FTS5_TOKENIZE_DOCUMENT - A document is being inserted into ** or removed from the FTS table. The tokenizer is being invoked to ** determine the set of tokens to add to (or delete from) the ** FTS index. *** FTS5_TOKENIZE_QUERY - A MATCH query is being executed ** against the FTS index. The tokenizer is being called to tokenize ** a bareword or quoted string specified as part of the query. *** (FTS5_TOKENIZE_QUERY | FTS5_TOKENIZE_PREFIX) - Same as ** FTS5_TOKENIZE_QUERY, except that the bareword or quoted string is ** followed by a "*" character, indicating that the last token ** returned by the tokenizer will be treated as a token prefix. *** FTS5_TOKENIZE_AUX - The tokenizer is being invoked to ** satisfy an fts5_api.xTokenize() request made by an auxiliary ** function. Or an fts5_api.xColumnSize() request made by the same ** on a columsize=0 database. *** ** For each token in the input string, the supplied callback xToken() must ** be invoked. The first argument to it should be a copy of the pointer ** passed as the second argument to xTokenize(). The third and fourth ** arguments are a pointer to a buffer containing the token text, and the ** size of the token in bytes. The 4th and 5th arguments are the byte offsets ** of the first byte of and first byte immediately following the text from ** which the token is derived within the input. *** The second argument passed to the xToken() callback ("tflags") should ** normally be set to 0. The exception is if the tokenizer supports ** synonyms. In this case see the discussion below for details. *** FTS5 assumes the xToken() callback is invoked for each token in the ** order that they occur within the input text. *** If an xToken() callback returns any value other than SQLITE_OK, then ** the tokenization should be abandoned and the xTokenize() method should ** immediately return a copy of the xToken() return value. Or, if the ** input buffer is exhausted, xTokenize() should return SQLITE_OK. Finally, ** if an error occurs with the xTokenize() implementation itself, it ** may abandon the tokenization and return any error code other than ** SQLITE_OK or SQLITE_DONE. *** SYNONYM SUPPORT *** Custom tokenizers may also support synonyms. Consider a case in which a ** user wishes to query for a phrase such as "first place". Using the ** built-in tokenizers, the FTS5 query 'first + place' will match instances ** of "first place" within the document set, but not alternative forms ** such as "1st place". In some applications, it would be better to match ** all instances of "first place" or "1st place" regardless of which form ** the user specified in the MATCH query text. *** There are several ways to approach this in FTS5: *** By mapping all synonyms to a single token. In this case, the ** In the above example, this means that the tokenizer returns the ** same token for inputs "first" and "1st". Say that token is in ** fact "first", so that when the user inserts the document "I won ** 1st place" entries are added to the index for tokens "i", "won", ** "first" and "place". If the user then queries for '1st + place', ** the tokenizer substitutes "first" for "1st" and the query works ** as expected. *** By adding multiple synonyms for a single term to the FTS index. ** In this case, when tokenizing query text, the tokenizer may ** provide multiple synonyms for a single term within the document. ** FTS5 then queries the index for each synonym individually. For ** example, faced with the query: *** <codeblock> ** ... MATCH 'first place'</codeblock> ** ** the tokenizer offers both "1st" and "first" as synonyms for the ** first token in the MATCH query and FTS5 effectively runs a query ** similar to: *** <codeblock> ** ... MATCH ('first OR 1st') place</codeblock> ** ** except that, for the purposes of auxiliary functions, the query ** still appears to contain just two phrases - "(first OR 1st)" ** being treated as a single phrase. *** By adding multiple synonyms for a single term to the FTS index. ** Using this method, when tokenizing document text, the tokenizer ** provides multiple synonyms for each token. So that when a ** document such as "I won first place" is tokenized, entries are ** added to the FTS index for "i", "won", "first", "1st" and ** "place". ** ** This way, even if the tokenizer does not provide synonyms ** when tokenizing query text (it should not - to do would be ** inefficient), it doesn't matter if the user queries for ** 'first + place' or '1st + place', as there are entries in the ** FTS index corresponding to both forms of the first token. ** ** ** Whether it is parsing document or query text, any call to xToken that ** specifies a <i>tflags</i> argument with the FTS5_TOKEN_COLOCATED bit ** is considered to supply a synonym for the previous token. For example, ** when parsing the document "I won first place", a tokenizer that supports ** synonyms would call xToken() 5 times, as follows: *** <codeblock> ** xToken(pCtx, 0, "i", 1, 0, 1); ** xToken(pCtx, 0, "won", 3, 2, 5); ** xToken(pCtx, 0, "first", 5, 6, 11); ** xToken(pCtx, FTS5_TOKEN_COLOCATED, "1st", 3, 6, 11); ** xToken(pCtx, 0, "place", 5, 12, 17); ** </codeblock> ** ** It is an error to specify the FTS5_TOKEN_COLOCATED flag the first time ** xToken() is called. Multiple synonyms may be specified for a single token ** by making multiple calls to xToken(FTS5_TOKEN_COLOCATED) in sequence. ** There is no limit to the number of synonyms that may be provided for a ** single token. ** ** In many cases, method (1) above is the best approach. It does not add ** extra data to the FTS index or require FTS5 to query for multiple terms, ** so it is efficient in terms of disk space and query speed. However, it ** does not support prefix queries very well. If, as suggested above, the ** token "first" is substituted for "1st" by the tokenizer, then the query: *** <codeblock> ** ... MATCH '1s*'</codeblock> ** ** will not match documents that contain the token "1st" (as the tokenizer ** will probably not map "1s" to any prefix of "first"). *** ** For full prefix support, method (3) may be preferred. In this case, ** because the index contains entries for both "first" and "1st", prefix ** queries such as 'fi*' or '1s*' will match correctly. However, because ** extra entries are added to the FTS index, this method uses more space ** within the database. *** ** Method (2) offers a midpoint between (1) and (3). Using this method, ** a query such as '1s*' will match documents that contain the literal ** token "1st", but not "first" (assuming the tokenizer is not able to ** provide synonyms for prefixes). However, a non-prefix query like '1st' ** will match against "1st" and "first". This method does not require ** extra disk space, as no extra entries are added to the FTS index. ** On the other hand, it may require more CPU cycles to run MATCH queries, ** as separate queries of the FTS index are required for each synonym. ** ** When using methods (2) or (3), it is important that the tokenizer only ** provide synonyms when tokenizing document text (method (2)) or query ** text (method (3)), not both. Doing so will not cause any errors, but is ** inefficient.

69918. ***** Interface to code in fts5_varint.c.
69919. Set to true when thread finishes
69920. ** Collation sequence destructor function. The pCtx argument points to ** a UCollator structure previously allocated using ucol_open().
69921. ** Open a new Fts5Index handle. If the bCreate argument is true, create ** and initialize the underlying tables *** If successful, set *pp to point to the new object and return SQLITE_OK. ** Otherwise, set *pp to NULL and return an SQLite error code.
69922. Buffer to load terms into
69923. Set the usable flag on the subset of constraints identified by ** arguments mUsable and mExclude.
69924. Seek cursor iCur to the row to delete. If this row no longer exists ** (this can happen if a trigger program has already deleted it), do ** not attempt to delete it or fire any DELETE triggers.
69925. 153
69926. Construct the Index object to describe this index
69927. True after i'th new page is populated
69928. Open the connection to the log file. If this operation fails, ** (e.g. due to malloc() failure), return an error code.
69929. Common features
69930. The FROM clause term to search
69931. Size of term prefix in bytes
69932. Copy original pages out of the journal and back into the ** database file and/or page cache.
69933. ** Return the 'affinity' of the expression pExpr if any. *** If pExpr is a column, a reference to a column via an 'AS' alias, ** or a sub-select with a column as the return value, then the ** affinity of that column is returned. Otherwise, 0x00 is returned, ** indicating no affinity for the expression. *** i.e. the WHERE clause expressions in the following statements all ** have an affinity: *** CREATE TABLE t1(a); ** SELECT * FROM t1 WHERE a; ** SELECT a AS b FROM t1 WHERE b; ** SELECT * FROM t1 WHERE (select a from t1);
69934. A correlated subquery has been seen
69935. Allocated size of buffer z in bytes
69936. ***** End of utf.c *****
69937. **comment:** Unused opcode memory
label: code-design
69938. ** The DJGPP compiler environment looks mostly like Unix, but it ** lacks the fcntl() system call. So redefine fcntl() to be something ** that always succeeds. This means that locking does not occur under ** DJGPP. But it is DOS - what did you expect?
69939. Session object pTab is attached to
69940. setlist ::= LP idlist RP EQ expr
69941. A completely parsed JSON string
69942. ** Return the depth of a tree comprising nPMA PMAs, assuming a fanout of ** SORTER_MAX_MERGE_COUNT. The returned value does not include leaf nodes. *** i.e. *** nPMA<=16 -> TreeDepth() == 0 ** nPMA<=256 -> TreeDepth() == 1 ** nPMA<=65536 -> TreeDepth() == 2
69943. ** Kinds of hints that can be passed into the sqlite3BtreeCursorHint() ** interface. *** BTREE_HINT_RANGE (arguments: Expr*, Mem*) *** The first argument is an Expr* (which is guaranteed to be constant for ** the lifetime of the cursor) that defines constraints on which rows ** might be fetched with this cursor. The Expr* tree may contain ** TK_REGISTER nodes that refer to values stored in the array of registers ** passed as the second parameter. In other words, if Expr.op==TK_REGISTER ** then the value of the node is the value in Mem[pExpr.iTable]. Any ** TK_COLUMN node in the expression tree refers to the Expr.iColumn-th ** column of the b-tree of the cursor. The Expr tree will not contain ** any function calls nor subqueries nor references to b-trees other than ** the cursor being hinted. *** The design of the _RANGE hint is aid b-tree implementations that try ** to prefetch content from remote machines - to provide those ** implementations with limits on what needs to be prefetched and thereby ** reduce network bandwidth. *** Note that BTREE_HINT_FLAGS with BTREE_BULKLOAD is the only hint used by ** standard SQLite. The other hints are provided for extentions that use ** the SQLite parser and code generator but substitute their own storage ** engine.
69944. pSlot and pCArray->apCell[i] will never overlap on a well-formed ** database. But they might for a corrupt database. Hence use memmove() ** since memcpy() sends SIGABORT with overlapping buffers on OpenBSD
69945. Format string for SQL
69946. resolvetype ::= REPLACE
69947. Minimum file format for writable database files
69948. LOCATE_VIEW or LOCATE_NOERR
69949. Add the table to the in-memory representation of the database.
69950. OUT: First token of proposed snippet
69951. fts5YYNOERRORRECOVERY
69952. Return the sqlite3_file object for the WAL file
69953. Precomputed device characteristics
69954. Object to pass to xBestIndex()
69955. This is what we do if the grammar does not define ERROR: *** * Report an error message, and throw away the input token. *** * If the input token is \$, then fail the parse. *** As before, subsequent error messages are suppressed until ** three input tokens have been successfully shifted.
69956. ** Convert an ANSI string to Microsoft Unicode, using the ANSI or OEM ** code page. *** Space to hold the returned string is obtained from sqlite3_malloc().
69957. Mask of the bit in sqlite3.flags to set/clear
69958. Comparison operator
69959. ** The second parameter to sqlite3BtreeGetMeta or sqlite3BtreeUpdateMeta ** should be one of the following values. The integer values are assigned ** to constants so that the offset of the corresponding field in an ** SQLite database header may be found using the following formula: *** offset = 36 + (idx * 4) **
** For example, the free-page-count field is located at byte offset 36 of ** the database file header. The incr-vacuum-flag field is located at ** byte offset 64 (== 36+4*7). *** The BTREE_DATA_VERSION value is not really a value stored in the header. ** It is a read-only number computed by the pager. But we merge it with ** the header value access routines since its access pattern is the same. ** Call it a "virtual meta value".
69960. Run the program
69961. If this is an INSERT into a table b-tree and the table has an ** explicit INTEGER PRIMARY KEY, check that this is not an attempt ** to write a NULL into the IPK column. That is not permitted.
69962. Current tree root
69963. ** Return true if the p->aiException[] array contains the value iCode.

69964. Create a record from the argument register contents and insert it into ** the ephemeral table.
69965. List of dirty pages in LRU order
69966. ** CAPI3REF: Custom Page Cache Object ** ** The sqlite3_pcache type is opaque. It is implemented by ** the pluggable module. The SQLite core has no knowledge of ** its size or internal structure and never deals with the ** sqlite3_pcache object except by holding and passing pointers ** to the object. *** See [sqlite3_pcache_methods2] for additional information.
69967. ** This function is called while stepping or preparing a statement ** associated with connection db. The operation will return SQLITE_LOCKED ** to the user because it requires a lock that will not be available ** until connection pBlocker concludes its current transaction.
69968. ** The json_test1(JSON) function return true (1) if the input is JSON ** text generated by another json function. It returns (0) if the input ** is not known to be JSON.
69969. Do not write content to disk
69970. old.* record for second change
69971. Saved syscall error number
69972. Index of the column to extract
69973. 148
69974. Try to ORDER BY the result set to make distinct processing easier
69975. ** Close an open wal-index.
69976. Array of arguments
69977. Underlying VFS
69978. Saved value of p->iOffset
69979. Pseudo-random number used for sampling
69980. Value to return from this function
69981. True to run the ORDER BY search loop
69982. EXCLUSIVE
69983. Delete the index records
69984. Allocated size of aBuffer[] in bytes
69985. Number of slots in apHash[]
69986. "PRAGMA encoding"
69987. The database structure
69988. Tokenizer module
69989. The SQLITE_EXTRA_DURABLE compile-time option used to set the default ** synchronous setting to EXTRA. It is no longer supported.
69990. The expression mask set
69991. Year, month, and day
69992. Fire BEFORE or INSTEAD OF triggers
69993. xEof - check for end of scan
69994. xRowid - read data
69995. jump, in1
69996. ** Grow the db->aVTrans[] array so that there is room for at least one ** more v-table. Return SQLITE_NOMEM if a malloc fails, or SQLITE_OK otherwise.
69997. ** get2byteAligned(), unlike get2byte(), requires that its argument point to a ** two-byte aligned address. get2bytea() is only used for accessing the ** cell addresses in a btree header.
69998. The "wsdStat" macro will resolve to the status information ** state vector. If writable static data is unsupported on the target, ** we have to locate the state vector at run-time. In the more common ** case where writable static data is supported, wsdStat can refer directly ** to the "sqlite3Stat" state vector declared above.
69999. 830
70000. ** Execute zSql on database db. *** If zSql returns rows, then each row will have exactly one ** column. (This will only happen if zSql begins with "SELECT".) ** Take each row of result and call execSql() again recursively. *** The execSqlF() routine does the same thing, except it accepts ** a format string as its third argument
70001. The flattened query is distinct if either the inner or the ** outer query is distinct.
70002. Pager.pageSize bytes of space for tmp use
70003. Identify the output register
70004. Expression for MATCH queries
70005. ** The maximum number of attached databases. This must be between 0 ** and 125. The upper bound of 125 is because the attached databases are ** counted using a signed 8-bit integer which has a maximum value of 127 ** and we have to allow 2 extra counts for the "main" and "temp" databases.
70006. Used to iterate through pTrigger list
70007. One or more of FLAG_ constants below
70008. ** Free up as much memory as possible from the page cache.
70009. 132
70010. ** Flush the contents of in-memory hash table iHash to a new level-0 ** segment on disk. Also update the corresponding structure record. *** If an error occurs, set the Fts5Index.rc error code. If an error has ** already occurred, this function is a no-op.
70011. ** END OF CUSTOM TOKENIZERS *****
70012. Set up a new SrcList in pOrTab containing the table being scanned ** by this loop in the a[0] slot and all notReady tables in a[1..] slots. ** This becomes the SrcList in the recursive call to sqlite3WhereBegin().
70013. Set len to the maximum number of bytes required in the output buffer.
70014. The file descriptor for pFile
70015. If there were no rowids on the leaf page either and the doclist-index ** has already been started, append an 0x00 byte to it.
70016. Mask of TF_* values
70017. Opcode: IFNotZero P1 P2 * * * * Synopsis: if r[P1]!=0 then r[P1]--, goto P2 ** ** Register P1 must contain an integer. If the content of register P1 is ** initially greater than zero, then decrement the value in register P1. ** If it is non-zero (negative or positive) and then also jump to P2. ** If register P1 is initially zero, leave it unchanged and fall through.
70018. Value returned by sqlite3_total_changes()
70019. ** Turn bulk memory into a RowSet object. N bytes of memory ** are available at pSpace. The db pointer is used as a memory context ** for any subsequent allocations that need to occur. ** Return a pointer to the new RowSet object. *** It must be the case that N is sufficient to make a Rowset. If not ** an assertion fault occurs. *** If N is larger than the minimum, use the surplus as an initial ** allocation of entries available to be filled.
70020. Index of first token in snippet
70021. Release the reader lock held while backfilling
70022. Number of bits that are set - only valid for aHash ** element. Max is BITVEC_NINT. For BITVEC_SZ of 512, ** this would be 125.
70023. CAST => ID
70024. text encoding
70025. sqlite3WhereGetMask(&pWInfo->sMaskSet, iCur);
70026. number of named columns in virtual table
70027. ** Retrieve a page from the pager cache. If the requested page is not ** already in the pager cache return NULL. Initialize the MemPage.pBt and ** MemPage.aData elements if needed.
70028. Forward references to VFS helper methods used for temporary files
70029. ** This routine restores a cursor back to its original position after it ** has been moved by some outside activity (such as a btree rebalance or ** a row having been deleted out from under the cursor). *** On success, the *pDifferentRow parameter is false if the cursor is left ** pointing at exactly the same row. *pDifferntRow is the row the cursor ** was pointing to has been deleted, forcing the cursor to point to some ** nearby row. *** This routine should only be called for a cursor that just returned ** TRUE from sqlite3BtreeCursorHasMoved().
70030. expr ::= expr EQ|NE expr
70031. The data for the record immediately follows this header
70032. Calling function guarantees this much

70033. Empty output segment. This is a no-op.
70034. ** Sync an rbuVfs-file.
70035. b
70036. Starter space for aArg[]. No malloc required
70037. Allocate space for the WalIterator object.
70038. refarg ::= ON DELETE refact
70039. INNER
70040. typename ::= typename ID|STRING
70041. Zero or more SQLITE_PREPARE_* flags
70042. To avoid deadlock, first release all locks with a larger ** BtShared address. Then acquire our lock. Then reacquire ** the other BtShared locks that we used to hold in ascending ** order.
70043. testcase(IS_BIG_INT(iOffset)); // requires a 4GiB WAL
70044. In test mode, increase the size of this structure a bit so that ** it is larger than the struct CrashFile defined in test6.c.
70045. IN/OUT: Readr offset in pTask->file
70046. ** Close a connection to shared-memory. Delete the underlying ** storage if deleteFlag is true.
70047. now generate the new WHERE rowid IN clause for the DELETE/UPDATE
70048. ** CAPI3REF: Virtual Table Configuration Options *** These macros define the various options to the ** [sqlite3_vtab_config0] interface that [virtual table] implementations ** can use to customize and optimize their behavior. *** <dl> ** <dt>SQLITE_VTAB_CONSTRAINT_SUPPORT ** <dd>Calls of the form ** [sqlite3_vtab_config](db,SQLITE_VTAB_CONSTRAINT_SUPPORT,X) are supported, ** where X is an integer. If X is zero, then the [virtual table] whose ** [xCreate] or [xConnect] method invoked [sqlite3_vtab_config()] does not ** support constraints. In this configuration (which is the default) if ** a call to the [xUpdate] method returns [SQLITE_CONSTRAINT], then the entire ** statement is rolled back as if [ON CONFLICT | OR ABORT] had been ** specified as part of the users SQL statement, regardless of the actual ** ON CONFLICT mode specified. *** If X is non-zero, then the virtual table implementation guarantees ** that if [xUpdate] returns [SQLITE_CONSTRAINT], it will do so before ** any modifications to internal or persistent data structures have been made. ** If the [ON CONFLICT] mode is ABORT, FAIL, IGNORE or ROLLBACK, SQLite ** is able to roll back a statement or database transaction, and abandon ** or continue processing the current SQL statement as appropriate. ** If the ON CONFLICT mode is REPLACE and the [xUpdate] method returns ** [SQLITE_CONSTRAINT], SQLite handles this as if the ON CONFLICT mode ** had been ABORT. *** Virtual table implementations that are required to handle OR REPLACE ** must do so within the [xUpdate] method. If a call to the ** [sqlite3_vtab_on_conflict()] function indicates that the current ON ** CONFLICT policy is REPLACE, the virtual table implementation should ** silently replace the appropriate rows within the xUpdate callback and ** return SQLITE_OK. Or, if this is not possible, it may return ** SQLITE_CONSTRAINT, in which case SQLite falls back to OR ABORT ** constraint handling. ** </dl>
70049. SQLITE_STMTSTATUS_VM_STEP
70050. Set the WHERE_ONEROW flag if the xBestIndex() method indicated ** that the scan will visit at most one row. Clear it otherwise.
70051. ** Code an OP_Halt due to non-unique rowid.
70052. The BtShared object that owns pPage
70053. Make sure the ordering..
70054. ** The sqlite3KeywordCode function looks up an identifier to determine if ** it is a keyword. If it is a keyword, the token code of that keyword is ** returned. If the input is not a keyword, TK_ID is returned. *** The implementation of this routine was generated by a program, ** mkkeywordhash.c, located in the tool subdirectory of the distribution. ** The output of the mkkeywordhash.c program is written into a file ** named keywordhash.h and then included into this source file by ** #include below.
70055. Called only by OP_MaxPgcnt
70056. xSetSystemCall
70057. Address of the OP_Jump opcode
70058. ** Stub routines for all mutex methods. *** This routines provide no mutual exclusion or error checking.
70059. ** The sqlite3ValueBytes() routine returns the number of bytes in the ** sqlite3_value object assuming that it uses the encoding "enc". ** The valueBytes() routine is a helper function.
70060. ** Assign VdbeCursor index numbers to all tables in a SrcList
70061. SQLITE_ENABLE_DBSTAT_VTAB
70062. Busy callback
70063. List of global functions to be inserted
70064. ***** End of where.c *****
70065. **comment:** Processing for aggregates with GROUP BY is very different and ** much more complex than aggregates without a GROUP BY.
 label: code-design
70066. ** Return TRUE if the pager is in a state where it is OK to change the ** journalmode. Journalmode changes can only happen when the database ** is unmodified.
70067. ** Link the chunk at mem5.aPool[i] so that is on the iLogsize ** free list.
70068. ** This function is the implementation of the xUpdate callback used by ** FTS3 virtual tables. It is invoked by SQLite each time a row is to be ** inserted, updated or deleted.
70069. Destructor for the aux data
70070. Skip past any whitespace
70071. **comment:** First register in temporary register block
 label: code-design
70072. One usually wants to use hw.acctivecpu for MT decisions, but not here
70073. Add this many bytes to each in-memory page
70074. If the first page of the wal-index has been mapped, try to read the ** wal-index header immediately, without holding any lock. This usually ** works, but may fail if the wal-index header is corrupt or currently ** being modified by another thread or process.
70075. ** These macros define the location of the pointer-map entry for a ** database page. The first argument to each is the number of usable ** bytes on each page of the database (often 1024). The second is the ** page number to look up in the pointer map. *** PTRMAP_PAGENO returns the database page number of the pointer-map ** page that stores the required pointer. PTRMAP_PTROFFSET returns ** the offset of the requested map entry. *** If the pgno argument passed to PTRMAP_PAGENO is a pointer-map page, ** then pgno is returned. So (pgno==PTRMAP_PAGENO(pgsz, pgno)) can be ** used to test if pgno is a pointer-map page. PTRMAP_ISPAGE implements ** this test.
70076. **comment:** The following loop copies up to p->nBuffer bytes per iteration into ** the p->aAlloc[] buffer.
 label: code-design

70195. Database page number to read data for
70196. Scratch allocations
70197. Verify that no lookaside memory was used by schema tables
70198. ** information about each column of an SQL table is held in an instance ** of this structure.
70199. 4x
70200. A boolean value
70201. Number of enterances
70202. Index of column in table
70203. ** An instance of this structure can hold a simple list of identifiers, ** such as the list "a,b,c" in the following statements: ** ** INSERT INTO t(a,b,c) VALUES ...; ** CREATE INDEX idx ON t(a,b,c); ** CREATE TRIGGER trig BEFORE UPDATE ON t(a,b,c) ...; ** ** The IdList.a.idx field is used when the IdList represents the list of ** column names after a table name in an INSERT statement. In the statement ** ** INSERT INTO t(a,b,c) ...; ** ** If "a" is the k-th column of table "t", then IdList.a[0].idx==k.
70204. Next are the tables used to determine what action to take based on the ** current state and lookahead token. These tables are used to implement ** functions that take a state number and lookahead value and return an ** action integer. ** ** Suppose the action integer is N. Then the action is determined as ** follows ** ** 0 <= N <= YY_MAX_SHIFT Shift N. That is, push the lookahead ** token onto the stack and goto state N. ** ** N between YY_MIN_SHIFTREDUCE Shift to an arbitrary state then ** and YY_MAX_SHIFTREDUCE reduce by rule N-YY_MIN_SHIFTREDUCE. ** ** N between YY_MIN_REDUCE Reduce by rule N-YY_MIN_REDUCE ** and YY_MAX_REDUCE ** ** N == YY_ERROR_ACTION A syntax error has occurred. ** ** N == YY_ACCEPT_ACTION The parser accepts its input. ** ** N == YY_NO_ACTION No such action. Denotes unused ** slots in the yy_action[] table. ** ** The action table is constructed as a single large table named yy_action[]. ** Given state S and lookahead X, the action is computed as either: ** ** (A) N = yy_action[yy_shift_ofst[S] + X] ** (B) N = yy_default[S] ** ** The (A) formula is preferred. The B formula is used instead if: ** (1) The yy_shift_ofst[S]+X value is out of range, or ** (2) yy_lookahead[yy_shift_ofst[S]+X] is not equal to X, or ** (3) yy_shift_ofst[S] equal YY_SHIFT_USE_DFLT. ** (Implementation note: YY_SHIFT_USE_DFLT is chosen so that ** YY_SHIFT_USE_DFLT+X will be out of range for all possible lookahead X. ** Hence only tests (1) and (2) need to be evaluated.) ** ** The formulas above are for computing the action when the lookahead is ** a terminal symbol. If the lookahead is a non-terminal (as occurs after ** a reduce

action) then the yy_reduce_ofst[] array is used in place of ** the yy_shift_ofst[] array and YY_REDUCE_USE_DFLT is used in place of ** YY_SHIFT_USE_DFLT. *** The following are the tables generated in this section: *** yy_action[] A single table containing all actions. ** yy_lookahead[] A table containing the lookahead for each entry in ** yy_action. Used to detect hash collisions. ** yy_shift_ofst[] For each state, the offset into yy_action for ** shifting terminals. ** yy_reduce_ofst[] For each state, the offset into yy_action for ** shifting non-terminals after a reduce. ** yy_default[] Default action for each state. *** ***** Begin parsing tables *****

70205. ** Advance the iterator passed as the second argument until it is at or ** past rowid iFrom. Regardless of the value of iFrom, the iterator is ** always advanced at least once.
70206. Checksum based on %_content contents
70207. If the TERM_LIKECOND flag is set, that means that the range search ** is sufficient to guarantee that the LIKE operator is true, so we ** can skip the call to the like(A,B) function. But this only works ** for strings. So do not skip the call to the function on the pass ** that compares BLOBS.
70208. Opcode: Eq P1 P2 P3 P4 P5 *** Synopsis: IF r[P3]==r[P1] *** Compare the values in register P1 and P3. If reg(P3)==reg(P1) then ** jump to address P2. Or if the SQLITE_STOREP2 flag is set in P5, then ** store the result of comparison in register P2. *** The SQLITE_AFF_MASK portion of P5 must be an affinity character - ** SQLITE_AFF_TEXT, SQLITE_AFF_INTEGER, and so forth. An attempt is made ** to coerce both inputs according to this affinity before the ** comparison is made. If the SQLITE_AFF_MASK is 0x00, then numeric ** affinity is used. Note that the affinity conversions are stored ** back into the input registers P1 and P3. So this opcode can cause ** persistent changes to registers P1 and P3. *** Once any conversions have taken place, and neither value is NULL, ** the values are compared. If both values are blobs then memcmp() is ** used to determine the results of the comparison. If both values ** are text, then the appropriate collating function specified in ** P4 is used to do the comparison. If P4 is not specified then ** memcmp() is used to compare text string. If both values are ** numeric, then a numeric comparison is used. If the two values ** are of different types, then numbers are considered less than ** strings and strings are considered less than blobs. *** If SQLITE_NULLEQ is set in P5 then the result of comparison is always either ** true or false and is never NULL. If both operands are NULL then the result ** of comparison is true. If either operand is NULL then the result is false. ** If neither operand is NULL the result is the same as it would be if ** the SQLITE_NULLEQ flag were omitted from P5. *** If both SQLITE_STOREP2 and SQLITE_KEEPNULL flags are set then the ** content of r[P2] is only changed if the new value is NULL or 0 (false). ** In other words, a prior r[P2] value will not be overwritten by 1 (true).

70261. ** CAPI3REF: Mutex Verification Routines *** The sqlite3_mutex_held() and sqlite3_mutex_noheld() routines ** are intended for use inside assert() statements. The SQLite core ** never uses these routines except inside an assert() and applications ** are advised to follow the lead of the core. The SQLite core

only ** provides implementations for these routines when it is compiled ** with the SQLITE_DEBUG flag. External mutex implementations ** are only required to provide these routines if SQLITE_DEBUG is ** defined and if NDEBUG is not defined. ** ** These routines should return true if the mutex in their argument ** is held or not held, respectively, by the calling thread. ** ** The implementation is not required to provide versions of these ** routines that actually work. If the implementation does not provide working ** versions of these routines, it should at least provide stubs that always ** return true so that one does not get spurious assertion failures. ** ** If the argument to sqlite3_mutex_held() is a NULL pointer then ** the routine should return 1. This seems counter-intuitive since ** clearly the mutex cannot be held if it does not exist. But ** the reason the mutex does not exist is because the build is not ** using mutexes. And we do not want the assert() containing the ** call to sqlite3_mutex_held() to fail, so a non-zero return is ** the appropriate thing to do. The sqlite3_mutex_notheld() ** interface should also return 1 when given a NULL pointer.

70262. A SELECT statement to use as the data source

70263. Size limit for persistent journal files

70264. ** Added for 3.7.4

70265. Array of first token in each sentence

70266. Cursor of the canonical data source

70267. 181

70268. ** Locate and return an entry from the db.aCollSeq hash table. If the entry ** specified by zName and nName is not found and parameter 'create' is ** true, then create a new entry. Otherwise return NULL. ** ** Each pointer stored in the sqlite3.aCollSeq hash table contains an ** array of three CollSeq structures. The first is the collation sequence ** preferred for UTF-8, the second UTF-16le, and the third UTF-16be. ** ** Stored immediately after the three collation sequences is a copy of ** the collation sequence name. A pointer to this string is stored in ** each collation sequence structure.

70269. A no-op destructor

70270. iVersion

70271. Otherwise, flush the current node of layer iLayer to disk. ** Then allocate a new, empty sibling node. The key will be written ** into the parent of this node.

70272. Begin scanning through hash table entries. This loop runs once for each ** term/doclist currently stored within the hash table.

70273. Do nothing if table already exists

70274. Clear all content from pragma virtual table cursor.

70275. jumps if either operand is NULL

70276. ** Manage pPage's participation on the dirty list. Bits of the addRemove ** argument determines what operation to do. The 0x01 bit means first ** remove pPage from the dirty list. The 0x02 means add pPage back to ** the dirty list. Doing both moves pPage to the front of the dirty list.

70277. Raw numeric value stored in s

70278. EVIDENCE-OF: R-36592-02772 The SQLITE_CONFIG_COVERING_INDEX_SCAN ** option takes a single integer argument which is interpreted as a ** boolean in order to enable or disable the use of covering indices for ** full table scans in the query optimizer.

70279. The vector. List of expressions or a sub-SELECT

70280. ** Take actions at the end of an API call to indicate an OOM error

70281. ** Advance to the next element in the sorter. Return value: ** ** SQLITE_OK success ** SQLITE_DONE end of data ** otherwise some kind of error.

70333. OUT: Map of index columns in pFKey
70334. Search the rowid of the table
70335. **comment:** ** All individual term iterators in pNear are guaranteed to be valid when ** this function is called. This function checks if all term iterators ** point to the same rowid, and if not, advances them until they do. ** If an EOF is reached before this happens, *pbEof is set to true before ** returning. *** ** SQLITE_OK is returned if an error occurs, or an SQLite error code ** otherwise. It is not considered an error code if an iterator reaches ** EOF.
label: code-design
70336. EACH => ID
70337. Address of opcode that determines the IN is true
70338. If the temp database has been explicitly named as part of the ** pragma, make sure it is open.
70339. ** The maximum number of opcodes in a VDBE program. ** Not currently enforced.
70340. WHERE clause on PK columns
70341. Compensate for pPager->iDataVersion++;
70342. Copy of pStr1 - RHS of LIKE/GLOB operator
70343. Generate code that executes if the new index entry is not unique
70344. Skip leading zeros.
70345. Pointer to a new child page
70346. If the user has configured a chunk-size for this file, truncate the ** file so that it consists of an integer number of chunks (i.e. the ** actual file size after the operation may be larger than the requested ** size).
70347. Total number of I/O Errors
70348. IGNORE => ID
70349. Object to return
70350. Create an Expr object representing an SQL expression like: *** <parent-key1> = <child-key1> AND <parent-key2> = <child-key2> ... *** ** The collation sequence used for the comparison should be that of ** the parent key columns. The affinity of the parent key column should ** be applied to each child key value before the comparison takes place.
70351. Result written here
70352. ** Return the page number associated with frame iFrame in this WAL.
70353. ** This is called when the database connection passed as an argument is ** being closed. The connection is removed from the blocked list.
70354. The point is to increment the last character before the first ** wildcard. But if we increment '@', that will push it into the ** alphabetic range where case conversions will mess up the ** inequality. To avoid this, make sure to also run the full ** LIKE on all candidate expressions by clearing the isComplete flag
70355. Remove trailing zeros and the "." if no digits follow the ".".
70356. Mask of events to be traced
70357. Current lock held on database file
70358. __QNXNTO__
70359. Insert on a main table b-tree
70360. ** CAPI3REF: Obtaining SQL Values ** METHOD: sqlite3_value ** ** Summary: ** <blockquote><table border=0 cellpadding=0 cellspacing=0> ** <tr><td>sqlite3_value_blob<td>→;<td>BLOB value ** <tr><td>sqlite3_value_double<td>→;<td>REAL value ** <tr><td>sqlite3_value_int<td>→;<td>32-bit INTEGER value ** <tr><td>sqlite3_value_int64<td>→;<td>64-bit INTEGER value ** <tr><td>sqlite3_value_pointer<td>→;<td>Pointer value ** <tr><td>sqlite3_value_text<td>→;<td>UTF-8 TEXT value ** <tr><td>sqlite3_value_text16<td>→;<td>UTF-16 TEXT value in ** the native byteorder ** <tr><td>sqlite3_value_text16be<td>→;<td>UTF-16be TEXT value ** <tr><td>sqlite3_value_text16le<td>→;<td>UTF-16le TEXT value ** <tr><td> <td> ** <tr><td>sqlite3_value_bytes<td>→;<td>Size of a BLOB ** or a UTF-8 TEXT in bytes ** <tr><td>sqlite3_value_bytes16 </td> ** <td>→; <td>Size of UTF-16 ** TEXT in bytes ** <tr><td>sqlite3_value_type→;<td>Default ** datatype of the value ** <tr><td>sqlite3_value_numeric_type </td> ** <td>→; <td>Best numeric datatype of the value ** </table></blockquote> ** ** Details: ** ** These routines extract type, size, and content information from ** [protected sqlite3_value] objects. Protected sqlite3_value objects ** are used to pass parameter information into implementation of ** [application-defined SQL functions] and [virtual tables]. *** ** These routines work only with [protected sqlite3_value] objects. ** Any attempt to use these routines on an [unprotected sqlite3_value] ** is not threadsafe. *** ** ^These routines work just like the corresponding [column access functions] ** except that these routines take a single [protected sqlite3_value] object ** pointer instead of a [sqlite3_stmt*] pointer and an integer column number. *** ** ^The sqlite3_value_text16() interface extracts a UTF-16 string ** in the native byte-order of the host machine. ^The ** sqlite3_value_text16be() and sqlite3_value_text16le() interfaces ** extract UTF-16 strings as big-endian and little-endian respectively. *** ** ^If [sqlite3_value]

object V was initialized ** using [sqlite3_bind_pointer(S,I,P,X,D)] or [sqlite3_result_pointer(C,P,X,D)] ** and if X and Y are strings that compare equal according to strcmp(X,Y), ** then sqlite3_value_pointer(V,Y) will return the pointer P. ^Otherwise, ** sqlite3_value_pointer(V,Y) returns a NULL. The sqlite3_bind_pointer() ** routine is part of the [pointer passing interface] added for SQLite 3.20.0. *** ^The sqlite3_value_type(V) interface returns the ** [SQLITE_INTEGER | datatype code] for the initial datatype of the ** [sqlite3_value] object V. The returned value is one of [SQLITE_INTEGER], ** [SQLITE_FLOAT], [SQLITE_TEXT], [SQLITE_BLOB], or [SQLITE_NULL].^ ** Other interfaces might change the datatype for an sqlite3_value object. ** For example, if the datatype is initially SQLITE_INTEGER and ** sqlite3_value_text(V) is called to extract a text value for that ** integer, then subsequent calls to sqlite3_value_type(V) might return ** SQLITE_TEXT. Whether or not a persistent internal datatype conversion ** occurs is undefined and may change from one release of SQLite to the next. *** ^The sqlite3_value_numeric_type() interface attempts to apply ** numeric affinity to the value. This means that an attempt is ** made to convert the value to an integer or floating point. If ** such a conversion is possible without loss of information (in other ** words, if the value is a string that looks like a number) ** then the conversion is performed. Otherwise no conversion occurs. ** The [SQLITE_INTEGER | datatype] after conversion is returned.)^ ** Please pay particular attention to the fact that the pointer returned ** from [sqlite3_value_blob()], [sqlite3_value_text()], or ** [sqlite3_value_text16()] can be invalidated by a subsequent call to ** [sqlite3_value_bytes()], [sqlite3_value_bytes16()], [sqlite3_value_text()], ** or [sqlite3_value_text16()]. ** These routines must be called from the same thread as ** the SQL function that supplied the [sqlite3_value*] parameters.

70361. Number of cells
70362. ** Close an RBU handle. *** If the RBU update has been completely applied, mark the RBU database ** as fully applied. Otherwise, assuming no error has occurred, save the ** current state of the RBU update application to the RBU database. *** If an error has already occurred as part of an sqlite3rbu_step() ** or sqlite3rbu_open() call, or if one occurs within this function, an ** SQLite error code is returned. Additionally, if pzErrmsg is not NULL, ** *pzErrmsg may be set to point to a buffer containing a utf-8 formatted ** English language error message. It is the responsibility of the caller to ** eventually free any such buffer using sqlite3_free(). *** Otherwise, if no error occurs, this function returns SQLITE_OK if the ** update has been partially applied, or SQLITE_DONE if it has been ** completely applied.
70363. ** An array of names of all compile-time options. This array should ** be sorted A-Z. *** This array looks large, but in a typical installation actually uses ** only a handful of compile-time options, so most times this array is usually ** rather short and uses little memory space.
70364. Number of fields in the table or index
70365. Unpacked version of new.* record
70366. LIKE_KW => ID
70367. Jump here to exit loop
70368. Single VALUES term with multiple rows
70369. Changes whenever database content changes
70370. Size of vectors for this IN operator
70371. 0x16
70372. Output string - not real JSON
70373. ** Calling this function indicates that subsequent calls to ** fts3PendingTermsAdd() are to add term/position-list pairs for the ** contents of the document with docid iDocid.
70374. If non-NULL, points to sqlite3_vtab.base.zErrmsg. Often NULL.
70375. xFunc, void*
70376. EVIDENCE-OF: R-19854-42126 There are three arguments to ** SQLITE_CONFIG_HEAP: An 8-byte aligned pointer to the memory, the ** number of bytes in the memory buffer, and the minimum allocation size.
70377. ** This routine takes the module argument that has been accumulating ** in pParse->zArg[] and appends it to the list of arguments on the ** virtual table currently under construction in pParse->pTable.
70378. ** Return a pointer to the symbol zSymbol in the dynamic library pHandle.
70379. Index into mem5.aiFreelist[]
70380. Value to bind
70381. Append the position lists
70382. Above requires no mutex. Use mutex below for variable that follow.
70383. ** Convert a DbPage obtained from the pager into a MemPage used by ** the btree layer.
70384. True if we are at the end of input
70385. Estimated rows returned by this scan
70386. Cannot start a write transaction without first holding a read ** transaction.
70387. Cursor used to scan change record
70388. Function name (nul-terminated)
70389. Table columns
70390. ** This function returns a pointer to a nul-terminated string in memory ** obtained from sqlite3DbMalloc(). If sqlite3.nVdbeExec is 1, then the ** string contains a copy of zRawSql but with host parameters expanded to ** their current bindings. Or, if sqlite3.nVdbeExec is greater than 1, ** then the returned string holds a copy of zRawSql with "-- " prepended ** to each line of text. *** If the SQLITE_TRACE_SIZE_LIMIT macro is defined to an integer, then ** then long strings and blobs are truncated to that many bytes. This ** can be used to prevent unreasonably large trace strings when dealing ** with large (multi-megabyte) strings and blobs. *** The calling function is responsible for making sure the memory returned ** is eventually freed. ** ** ALGORITHM: Scan the input string looking for host parameters in any of ** these forms: ?, ?N, \$A, @A, :A. Take care to avoid text within ** string literals, quoted identifier names, and comments. For text forms, ** the host parameter index is found by scanning the prepared ** statement for the corresponding OP_Variable opcode. Once the host ** parameter index is known, locate the value in p->aVar[]. Then render ** the value as a literal in place of the host parameter name.
70391. Rowid in main table of the key
70392. If the RHS begins with a digit or a minus sign, then the LHS must ** be an ordinary column (not a virtual table column) with TEXT affinity. ** Otherwise the LHS might be numeric and "lhs >= rhs" would be false ** even though "lhs LIKE rhs" is true. But if the RHS does not start ** with a digit or '-', then "lhs LIKE rhs" will always be false if ** the LHS is numeric and so the optimization still works.
70393. ** Free memory. *** The outer layer memory allocator prevents this routine from ** being called with pPrior==0.
70394. ** Set the "use-threads" flag on object pIncr.
70395. ALTER
70396. The escape char (LIKE) or 't' (GLOB)
70397. Pointer to buffer containing string
70398. Attempt to write a readonly database
70399. _PCACHE_H_
70400. Page to edit
70401. If unable to open an sqlite3_blob on the desired row, that can only ** be because the shadow tables hold erroneous data.
70402. Handle that must hold lock
70403. Mask of TRIGGER_BEFORE|TRIGGER_AFTER
70404. ***** End of btreeInt.h *****
70405. Forward Declarations
70406. True for json_tree(). False for json_each()
70407. **comment:** ** The fts3BestSnippet() function often selects snippets that end with a ** query term. That is, the final term of the snippet is always a term ** that requires highlighting. For example, if 'X' is a highlighted term ** and '.' is a non-highlighted term, BestSnippet() may select: ** ***X.....X ** ** This function "shifts" the beginning of the snippet forward in the ** document so that there are approximately the same number of ** non-highlighted terms to the right of the final highlighted term as there ** are to the left of the first highlighted term. For example, to this: ** ***X.....X.... ** ** This is done as part of extracting the snippet text, not when selecting ** the snippet. Snippet selection is done based on doclists only, so there ** is no way for fts3BestSnippet() to know whether or not the document ** actually contains terms that follow the final highlighted term.
label: documentation
70408. SQLITE_STATUS_PAGECACHE_USED
70409. Cache zFilename in the locking context (APP and dotlock override) for ** proxyLock activation is possible (remote proxy is based on db name) ** zFilename remains valid until file is closed, to support
70410. Write-ahead log connection

70411. content=? parameter (or NULL)
70412. The proposed effective sample is a prefix of sample aSample[iSamp]. ** Specifically, the shortest prefix of at least (1 + iTest%nField) ** fields that is greater than the previous effective sample.
70413. Mem address which causes query abort if positive
70414. Copy entry from i1
70415. Data associated with this element
70416. **comment:** A complete hash table is an instance of the following structure. ** The internals of this structure are intended to be opaque -- client ** code should not attempt to access or modify the fields of this structure ** directly. Change this structure only by using the routines below. ** However, many of the "procedures" and "functions" for modifying and ** accessing this structure are really macros, so we can't really make ** this structure opaque.

 70552. This is a pointer type. There may be a flag to indicate what to ** do with the pointer.
 70553. ccons ::= DEFAULT PLUS term
 70554. NATURAL
 70555. ** The following routine destroys a virtual machine that is created by ** the sqlite3_compile() routine. The integer returned is an SQLITE_** success/failure code that describes the result of executing the virtual ** machine. ** ** This routine sets the error code and string returned by ** sqlite3_errcode(), sqlite3_errmsg() and sqlite3_errmsg16().
 70556. index leaf
 70557. Mutex controlling the lock
 70558. ** Query the size of the file in bytes.
 70559. The full-text index is stored in a series of b+tree (-like) ** structures called segments which map terms to doclists. The ** structures are like b+trees in layout, but are constructed from the ** bottom up in optimal fashion and are not updatable. Since trees ** are built from the bottom up, things will be described from the ** bottom up. *** **** Varints **** ** The basic unit of encoding is a variable-length integer called a ** varint. We encode variable-length integers in little-endian order ** using seven bits * per byte as follows: ** ** KEY: ** A = 0xxxxxxx 7 bits of data and one flag bit ** B = 1xxxxxxxx 7 bits of data and one flag bit *** ** 7 bits - A ** 14 bits - BA ** 21 bits - BBA ** and so on. **** This is similar in concept to how sqlite encodes "varints" but ** the encoding is not the same. SQLite varints are big-endian ** are limited to 9 bytes in length whereas FTS3 varints are ** little-endian and can be up to 10 bytes in length (in theory). *** ** Example encodings: *** ** 1: 0x01 ** 127: 0x7f ** 128: 0x81 0x00 ** *** **** Document lists **** ** A doclist (document list) holds a docid-sorted list of hits for a ** given term. Doclists hold docids and associated token positions. ** A docid is the unique integer identifier for a single document. ** A position is the index of a word within the document. The first ** word of the document has a position of 0. ** ** FTS3 used to optionally store character offsets using a compile-time ** option. But that functionality is no longer supported. ** ** A doclist is stored like this: ** ** array { ** varint docid; (delta from previous doclist) ** array { (position list for column 0) ** varint position; (2 more than the delta from previous position) ** } ** array { ** varint POS_COLUMN; (marks start of position list for new column) ** varint column; (index of new column) ** array { ** varint position; (2 more than the delta from previous position) ** } ** } ** varint POS_END; (marks end of positions for this document. ** } *** ** Here, array { X } means zero or more occurrences of X, adjacent in ** memory. A "position" is an index of a token in the token stream ** generated by the tokenizer. Note that POS_END and POS_COLUMN occur ** in the same logical place as the position element, and act as sentinals ** ending a position list array. POS_END is 0. POS_COLUMN is 1. ** The positions numbers are not stored literally but rather as two more ** than the difference from the prior position, or the just the position plus ** 2 for the first position. Example: *** ** label: A B C D E F G H I J K ** value: 123 5 9 1 1 14 35 0 234 72 0 ** ** The 123 value is the first docid. For column zero in this document ** there are two matches at positions 3 and 10 (5-2 and 9-2+3). The 1 ** at D signals the start of a new column; the 1 at E indicates that the ** new column is column number 1. There are two positions at 12 and 45 ** (14-2 and 35-2+12). The 0 at H indicate the end-of-document. The ** 234 at I is the delta to next docid (357). It has one position 70 ** (72-2) and then terminates with the 0 at K. ** ** A "position-list" is the list of positions for multiple columns for ** a single docid. A "column-list" is the set of positions for a single ** column. Hence, a position-list consists of one or more column-lists, ** a document record consists of a docid followed by a position-list and ** a doclist consists of one or more document records. ** ** A bare doclist omits the position information, becoming an ** array of varint-encoded docids. *** **** Segment leaf nodes **** ** Segment leaf nodes store terms and doclists, ordered by term. Leaf ** nodes are written using LeafWriter, and read using LeafReader (to ** iterate through a single leaf node's data) and LeavesReader (to ** iterate through a segment's entire leaf layer). Leaf nodes have ** the format: *** ** varint iHeight; (height from leaf level, always 0) ** varint nTerm; (length of first term) ** char pTerm[nTerm]; (content of first term) ** varint nDoclist; (length of term's associated doclist) ** char pDoclist[nDoclist]; (content of doclist) ** array { ** (further terms are delta-encoded) ** varint nPrefix; (length of prefix shared with previous term) ** varint nSuffix; (length of unshared suffix) ** char pTermSuffix[nSuffix]; (unshared suffix of next term) ** varint nDoclist; (length of term's associated doclist) ** char pDoclist[nDoclist]; (content of doclist) ** } *** ** Here, array { X } means zero or more occurrences of X, adjacent in ** memory. ** ** Leaf nodes are broken into blocks which are stored contiguously in ** the %_segments table in sorted order. This means that when the end ** of a node is reached, the next term is in the node with the next ** greater node id. *** ** New data is spilled to a new leaf node when the current node ** exceeds LEAF_MAX bytes (default 2048). New data which itself is ** larger than STANDALONE_MIN (default 1024) is placed in a standalone ** node (a leaf node with a single term and doclist). The goal of ** these settings is to pack together groups of small doclists while ** making it efficient to directly access large doclists. The ** assumption is that large doclists represent terms which are more ** likely to be query targets. ** ** TODO(shess) It may be useful for blocking decisions to be more ** dynamic. For instance, it may make more sense to have a 2.5k leaf ** node rather than splitting into 2k and .5k nodes. My intuition is ** that this might extend through 2x or 4x the pagesize. *** **** Segment interior nodes **** ** Segment interior nodes store blockids for subtree nodes and terms ** to describe what data is stored by the each subtree. Interior ** nodes are written using InteriorWriter, and read using ** InteriorReader. InteriorWriters are created as needed when ** SegmentWriter creates new leaf nodes, or when an interior node ** itself grows too big and must be split. The format of interior ** nodes: *** ** varint iHeight; (height from leaf level, always >0) ** varint iBlockid; (block id of node's leftmost subtree) ** optional { ** varint nTerm; (length of first term) ** char pTerm[nTerm]; (content of first term) ** array { ** (further terms are delta-encoded) ** varint nPrefix; (length of shared prefix with previous term) ** varint nSuffix; (length of unshared suffix) ** char pTermSuffix[nSuffix]; (unshared suffix of next term) ** } ** } *** ** Here, optional { X } means an optional element, while array { X } ** means zero or more occurrences of X, adjacent in memory. ** ** An interior node encodes n terms separating n+1 subtrees. The ** subtree blocks are contiguous, so only the first subtree's blockid ** is encoded. The subtree at iBlockid will contain all terms less ** than the first term encoded (or all terms if no term is encoded). ** Otherwise, for terms greater than or equal to pTerm[i] but less ** than pTerm[i+1], the subtree for that term will be rooted at ** iBlockid+i. Interior nodes only store enough term data to ** distinguish adjacent children (if the rightmost term of the left ** child is "something", and the leftmost term of the right child is ** "wicked", only "w" is stored). ** ** New data is spilled to a new interior node at the same height when ** the current node exceeds INTERIOR_MAX bytes (default 2048). ** INTERIOR_MIN_TERMS (default 7) keeps large terms from monopolizing ** interior nodes and making the tree too skinny. The interior nodes ** at a given height are naturally tracked by interior nodes at ** height+1, and so on. *** **** Segment directory **** ** The segment directory in table %_segdir stores meta-information for ** merging and deleting segments, and also the root node of the ** segment's tree. *** ** The root node is the top node of the segment's tree after encoding ** the entire segment, restricted to ROOT_MAX bytes (default 1024). ** This could be either a leaf node or an interior node. If the top ** node requires more than ROOT_MAX bytes, it is flushed to %_segments ** and a new root interior node is generated (which should always fit ** within ROOT_MAX because it only needs space for 2 varints, the ** height and the blockid of the previous root). *** ** The meta-information in the segment directory is: ** level - segment level (see below) ** idx - index within level ** - (level, idx uniquely identify a segment) ** start_block - first leaf node ** leaves_end_block - last leaf node ** end_block - last block (including interior nodes) ** root - contents of root node ** ** If the root node is a leaf node, then start_block, ** leaves_end_block, and end_block are all 0. *** **** Segment merging **** ** To amortize update costs, segments are grouped into levels and ** merged in batches. Each increase in level represents exponentially ** more documents. *** ** New documents (actually, document updates) are tokenized and ** written individually (using LeafWriter) to a level 0 segment, with ** incrementing idx. When idx reaches MERGE_COUNT (default 16), all ** level 0 segments are merged into a single level 1 segment. Level 1 ** is populated like level 0, and eventually MERGE_COUNT level 1 ** segments are merged to a single level 2 segment (representing ** MERGE_COUNT*2 updates), and so on. ** ** A segment merge traverses all segments at a given level in ** parallel, performing a straightforward sorted merge. Since segment ** leaf nodes are written in to the %_segments table in order, this ** merge traverses the underlying sqlite disk structures efficiently. ** After the merge, all segment blocks from the merged level are ** deleted. ** ** MERGE_COUNT controls how often we merge segments. 16 seems to be ** somewhat of a sweet spot for insertion performance. 32 and 64 show ** very similar performance numbers to 16 on insertion, though they're ** a tiny bit slower (perhaps due to more overhead in merge-time ** sorting). 8 is about 20% slower than 16, 4 about 50% slower than ** 16, 2 about 66% slower than 16. ** ** At query time, high MERGE_COUNT increases the number of segments ** which need to be scanned and merged. For instance, with 100k docs ** inserted: *** ** MERGE_COUNT segments ** 16 25 ** 8 12 ** 4 10 ** 2 6 ** ** This appears to have only a moderate impact on queries for

very ** frequent terms (which are somewhat dominated by segment merge ** costs), and infrequent and non-existent terms still seem to be fast ** even with many segments. *** TODO(shess) That said, it would be nice to have a better query-side ** argument for MERGE_COUNT of 16. Also, it is possible/likely that ** optimizations to things like doclist merging will swing the sweet ** spot around. *** *** **** Handling of deletions and updates **** ** Since we're using a segmented structure, with no docid-oriented ** index into the term index, we clearly cannot simply update the term ** index when a document is deleted or updated. For deletions, we ** write an empty doclist (varint(docid) varint(POS_END)), for updates ** we simply write the new doclist. Segment merges overwrite older ** data for a particular docid with newer data, so deletes or updates ** will eventually overtake the earlier data and knock it out. The ** query logic likewise merges doclists so that newer data knocks out ** older data.

70560. Number of extra columns needed

70561. ** No-op routine for the parse-tree walker. ** ** When this routine is the Walker.xExprCallback then expression trees ** are walked without any actions being taken at each node. Presumably, ** when this routine is used for Walker.xExprCallback then ** Walker.xSelectCallback is set to do something useful for every ** subquery in the parser tree.

70562. The SQLite database connection

70563. Use the built-in recursive mutexes if they are available.

70564. ** Added for 3.5.8

70565. & result codes with this before returning

70566. Array of cells and sizes

70567. First instruction of interior of the loop

70568. Global (connection wide) data

70569. Pages in wal

70570. ** Turn a relative pathname into a full pathname. The relative path ** is stored as a nul-terminated string in the buffer pointed to by ** zPath. *** ** zOut points to a buffer of at least sqlite3_vfs.mxPathname bytes ** (in this case, MAX_PATHNAME bytes). The full-path is written to ** this buffer before returning.

70571. If nSeg is less than zero, then there is no level with at least ** nMin segments and no hint in the %_stat table. No work to do. ** Exit early in this case.

70572. ***** Begin file pager.c *****

70573. Number of compound terms processed so far

70574. If there are outstanding locks, do not actually close the file just ** yet because that would clear those locks. Instead, add the file ** descriptor to pInode->pUnused list. It will be automatically closed ** when the last lock is cleared.

70575. ** An rtree cursor object.

70576. When SQLITE_BUG_COMPATIBLE_20160819 is defined, unrecognized arguments ** to VACUUM are silently ignored. This is a back-out of a bug fix that ** occurred on 2016-08-19 (<https://www.sqlite.org/src/info/083f9e6270>). ** The buggy behavior is required for binary compatibility with some ** legacy applications.

70577. Before the first write, give the VFS a hint of what the final ** file size will be.

70578. ** SELECTTRACE_ENABLED will be either 1 or 0 depending on whether or not ** the Select query generator tracing logic is turned on.

70579. The cell to be inserted

70580. aSample[] for the upper bound

70581. One of PASSIVE, FULL and RESTART

70582. ** If an SQLITE_CONFIG_SQLLOG hook is registered and the VM has been run, ** invoke it.

70583. Opcode: IntegrityCk P1 P2 P3 P4 P5 *** Do an analysis of the currently open database. Store in ** register P1 the text of an error message describing any problems. ** If no problems are found, store a NULL in register P1. *** The register P3 contains one less than the maximum number of allowed errors. ** At most reg(P3) errors will be reported. ** In other words, the analysis stops as soon as reg(P1) errors are ** seen. Reg(P1) is updated with the number of errors remaining. *** The root page numbers of all tables in the database are integers ** stored in P4_INTARRAY argument. *** If P5 is not zero, the check is done on the auxiliary database ** file, not the main database file. *** This opcode is used to implement the integrity_check pragma.

70584. Buffer to append text to

70585. The new key

70586. Grow the Ft5Hash.aSlot[] array if necessary.

70587. If any BEFORE triggers were coded, then seek the cursor to the ** row to be deleted again. It may be that the BEFORE triggers moved ** the cursor or already deleted the row that the cursor was ** pointing to. *** Also disable the iIdxNoSeek optimization since the BEFORE trigger ** may have moved that cursor.

70588. Table into which text will be inserted

70589. Number of columns that show through to the output. ** Additional columns are used only as parameters to ** aggregate functions

70590. Block of regs holding rowid+data being inserted

70591. This table is not a VIEW

70592. Index of rbu_control column

70593. ** Write a 64-bit variable-length integer to memory starting at p[0]. ** The length of data written will be between 1 and FTS3_VARINT_MAX bytes. ** The number of bytes written is returned.

70594. ** Render a string given by "fmt" into the StrAccum object.

70595. Forward declarations

70596. Used by TK_AGG_COLUMN and TK_AGG_FUNCTION

70597. ifexists ::= IF EXISTS

70598. **comment:** Prevent unnecessary deep recursion when we run out of entries

label: code-design

70599. Set after incrementing the change-counter

70600. ** Implementation of the NULLIF(x,y) function. The result is the first ** argument if the arguments are different. The result is NULL if the ** arguments are equal to each other.

70601. 0x30..0x3F

70602. #include "vdbeInt.h"

70603. Return true if the argument is non-NULL and the WAL module is using ** heap-memory for the wal-index. Otherwise, if the argument is NULL or the ** WAL module is using shared-memory, return false.

70604. cmd ::= VACUUM nm

70605. Amount to increment (*pHash->pnByte) by

70606. "INSERT ... %_data VALUES(?,?)"

70607. Number of columns in the constructed index

70608. ** The first parameter is a pointer to an output buffer. The second ** parameter is a pointer to an integer that contains the offset at ** which to write into the output buffer. This function copies the ** nul-terminated string pointed to by the third parameter, zSignedIdent, ** to the specified offset in the buffer and updates *pldx to refer ** to the first byte after the last byte written before returning. *** If the string zSignedIdent consists entirely of alpha-numeric ** characters, does not begin with a digit and is not an SQL keyword, ** then it is copied to the output buffer exactly as it is. Otherwise, ** it is quoted using double-quotes.

70609. Database of the table

70610. Set the doNotSpill NOSYNC bit to 1. This is because we cannot allow ** a journal header to be written between the pages journaled by ** this function.

70611. ** Implementation of the json_mergepatch(JSON1,JSON2) function. Return a JSON ** object that is the result of running the RFC 7396 MergePatch() algorithm ** on the two arguments.

70612. column names. malloced

70692. ***** Begin file btree.c *****
70693. Memory register holding the rowid counter
70694. If the file was opened successfully, read the schema for the new database. ** If this fails, or if opening the file failed, then close the file and ** remove the entry from the db->aDb[] array. i.e. put everything back the way ** we found it.
70695. 24
70696. "neq" column of stat[34] entry
70697. Total number of bytes in the record
70698. OUT: Permissions to open file with
70699. It is safe to always return here, but the resulting tree ** would be unbalanced
70700. Iterator for this term
70701. The rtree may have between 1 and RTREE_MAX_DIMENSIONS dimensions.
70702. Load doclist-index for this leaf
70703. Memory cell used to store aggregate context
70704. Last character before the first wildcard
70705. ** Argument pTerm must be a synonym iterator.
70706. ** Wrapper around the pluggable caches xUnpin method. If the cache is ** being used for an in-memory database, this function is a no-op.
70707. Value returned by SetFilePointer()
70708. ** Valid values for the second argument to fts3SqlStmt().
70709. If this is an RBU vacuum operation and the state table was empty ** when this handle was opened, create the target database schema.
70710. ** Return the number of phrases in expression pExpr.
70711. ** The MergeEngine object is used to combine two or more smaller PMAs into ** one big PMA using a merge operation. Separate PMAs all need to be ** combined into one big PMA in order to be able to step through the sorted ** records in order. *** The aReadr[] array contains a PmaReader object for each of the PMAs being ** merged. An aReadr[] object either points to a valid key or else is at EOF. ** ("EOF" means "End Of File". When aReadr[] is at EOF there is no more data.) ** For the purposes of the paragraphs below, we assume that the array is ** actually N elements in size, where N is the smallest power of 2 greater ** to or equal to the number of PMAs being merged. The extra aReadr[] elements ** are treated as if they are empty (always at EOF). *** The aTree[] array is also N elements in size. The value of N is stored in ** the MergeEngine.nTree variable. *** The final (N/2) elements of aTree[] contain the results of comparing ** pairs of PMA keys together. Element i contains the result of ** comparing aReadr[2*i-N] and aReadr[2*i-N+1]. Whichever key is smaller, the ** aTree element is set to the index of it. *** For the purposes of this comparison, EOF is considered greater than any ** other key value. If the keys are equal (only possible with two EOF ** values), it doesn't matter which index is stored. *** The (N/4) elements of aTree[] that precede the final (N/2) described ** above contains the index of the smallest of each block of 4 PmaReaders. ** And so on. So that aTree[1] contains the index of the PmaReader that ** currently points to the smallest key value. aTree[0] is unused. *** Example: *** aReadr[0] -> Banana ** aReadr[1] -> Feijo ** aReadr[2] -> Elderberry ** aReadr[3] -> Currant ** aReadr[4] -> Grapefruit ** aReadr[5] -> Apple ** aReadr[6] -> Durian ** aReadr[7] -> EOF *** aTree[] = { X, 0, 0, 5, 0, 3, 5, 6 } *** The current element is "Apple" (the value of the key indicated by ** PmaReader 5). When the Next() operation is invoked, PmaReader 5 will ** be advanced to the next key in its segment. Say the next key is ** "Eggplant": *** aReadr[5] -> Eggplant *** The contents of aTree[] are updated first by comparing the new PmaReader ** 5 key to the current key of PmaReader 4 (still "Grapefruit"). The PmaReader ** 5 value is still smaller, so aTree[6] is set to 5. And so on up the tree. ** The value of PmaReader 6 - "Durian" - is now smaller than that of PmaReader ** 5, so aTree[3] is set to 6. Key 0 is smaller than key 6 (Banana < Durian), ** so the value written into element 1 of the array is 0. As follows: *** aTree[] = { X, 0, 0, 6, 0, 3, 5, 6 } *** In other words, each time we advance to the next sorter element, log2(N) ** key comparison operations are required, where N is the number of segments ** being merged (rounded up to the next power of 2).
70712. ** This routine runs an extensive test of the Bitvec code. *** The input is an array of integers that acts as a program ** to test the Bitvec. The integers are opcodes followed ** by 0, 1, or 3 operands, depending on the opcode. Another ** opcode follows immediately after the last operand. *** There are 6 opcodes numbered from 0 through 5. 0 is the ** "halt" opcode and causes the test to end. *** 0 Halt and return the number of errors ** 1 N S X Set N bits beginning with S and incrementing by X ** 2 N S X Clear N bits beginning with S and incrementing by X ** 3 N Set N randomly chosen bits ** 4 N Clear N randomly chosen bits ** 5 N S X Set N bits from S increment X in array only, not in bitvec ** ** The opcodes 1 through 4 perform set and clear operations are performed ** on both a Bitvec object and on a linear array of bits obtained from malloc. ** Opcode 5 works on the linear array only, not on the Bitvec. ** Opcode 5 is used to deliberately induce a fault in order to ** confirm that error detection works. *** At the conclusion of the test the linear array is compared ** against the Bitvec object. If there are any differences, ** an error is returned. If they are the same, zero is returned. *** If a memory allocation error occurs, return -1.
70713. Content for INT, REAL, and STRING
70714. ***** Begin file tokenize.c *****
70715. term
70716. ** Set the LIKEOPT flag on the 2-argument function with the given name.
70717. If we reach this point, it means that the database connection has ** closed all sqlite3_stmt and sqlite3_backup objects and has been ** passed to sqlite3_close (meaning that it is a zombie). Therefore, ** go ahead and free all resources.
70718. Bytes of available memory
70719. nRowLogEst set from sqlite_stat1
70720. Maximum first byte of cell for a 1-byte payload
70721. 233
70722. ** Return values of columns for the row at which the stmt_cursor ** is currently pointing.
70723. OUT: Trbul number of columns
70724. The size of a single frame
70725. Add opcodes to the prepared statement

70726. ** Do an authorization check using the code and arguments given. Return ** either SQLITE_OK (zero) or SQLITE_IGNORE or SQLITE_DENY. If SQLITE_DENY ** is returned, then the error count and error message in pParse are ** modified appropriately.

70727. Enter the mutexes

70728. Most sig. 32 bits of new offset

70729. Evaluate the equality constraints

70730. True to accumulate patches

70731. ** Flush any data cached by the writer object to the database. Free any ** allocations associated with the writer.

70732. ** Obtain a changeset object containing all changes recorded by the ** session object passed as the first argument. *** It is the responsibility of the caller to eventually free the buffer ** using sqlite3_free().

70733. Index of new.* value to retrieve

70734. Value returned by system call

70735. DISTINCT using indexes

70736. ** Return true (non-zero) if the input is an integer that is too large ** to fit in 32-bits. This macro is used inside of various testcase() ** macros to verify that we have tested SQLite for large-file support.

70737. Check to see if we need to create an sqlite_sequence table for ** keeping track of autoincrement keys.

70738. No candidate table+column was found. This can only occur ** on the second iteration

70739. ** Make sure the Tcl calling convention macro is defined. This macro is ** only used by test code and Tcl integration code.

70740. ** PRAGMA [schema.]lock_proxy_file ** PRAGMA [schema.]lock_proxy_file = ":auto:"|"lock_file_path" *** Return or set the value of the lock_proxy_file flag. Changing ** the value sets a specific file to be used for database access locks. **

70741. ** A read-lock must be held on the pager when this function is called. If ** the pager is in WAL mode and the WAL file currently contains one or more ** frames, return the size in bytes of the page images stored within the ** WAL frames. Otherwise, if this is not a WAL database or the WAL file ** is empty, return 0.

70742. Opcode: Yield P1 P2 * * * * Swap the program counter with the value in register P1. This ** has the effect of yielding to a coroutine. *** If the coroutine that is launched by this instruction ends with ** Yield or Return then continue to the next instruction. But if ** the coroutine launched by this instruction ends with ** EndCoroutine, then jump to P2 rather than continuing with the ** next instruction. *** See also: InitCoroutine

70743. Size of BTM vector

70744. ** Extract the next token from a tokenization cursor. The cursor must ** have been opened by a prior call to simpleOpen().

70745. Split operator. TK_AND or TK_OR

70746. Result of last comparison

70747. Address of the select-B coroutine

70748. The rowid we are to seek to

70749. Thread holding this mutex

70750. At this point this is probably a keyword. But for that to be true, ** the next byte must contain either whitespace, an open or close ** parenthesis, a quote character, or EOF.

70751. ** Enlarge the memory allocation on a StrAccum object so that it is ** able to accept at least N more bytes of text. *** Return the number of bytes of text that StrAccum is able to accept ** after the attempted enlargement. The value returned might be zero.

70752. There is now an entry for pExpr in pAggInfo->aCol[] (either ** because it was there before or because we just created it). ** Convert the pExpr to be a TK_AGG_COLUMN referring to that ** pAggInfo->aCol[] entry.

70753. ** This function is called by the VDBE to adjust the internal schema ** used by SQLite when the btree layer moves a table root page. The ** root-page of a table or index in database iDb has changed from iFrom ** to iTo. *** Ticket #1728: The symbol table might still contain information ** on tables and/or indices that are the process of being deleted. ** If you are unlucky, one of those deleted indices or tables might ** have the same rootpage number as the real table or index that is ** being moved. So we cannot stop searching after the first match ** because the first match might be for one of the deleted indices ** or tables and not the table/index that is actually being moved. ** We must continue looping until all tables and indices with ** rootpage==iFrom have been converted to have a rootpage of iTo ** in order to be certain that we got the right one.

70754. ** Read a single page from either the journal file (if isMainJrn==1) or ** from the sub-journal (if isMainJrn==0) and playback that page. ** The page begins at offset *pOffset into the file. The *pOffset ** value is increased to the start of the next page in the journal. *** The main rollback journal uses checksums - the statement journal does ** not. *** If the page number of the page record read from the (sub-)journal file ** is greater than the current value of Pager.dbSize, then playback is ** skipped and SQLITE_OK is returned. *** If pDone is not NULL, then it is a record of pages that have already ** been played back. If the page at *pOffset has already been played back ** (if the corresponding pDone bit is set) then skip the playback. ** Make sure the pDone bit corresponding to the *pOffset page is set ** prior to returning. *** If the page record is successfully read from the (sub-)journal file ** and played back, then SQLITE_OK is returned. If an IO error occurs ** while reading the record from the (sub-)journal file or while writing ** to the database file, then the IO error code is returned. If data ** is successfully read from the (sub-)journal file but appears to be ** corrupted, SQLITE_DONE is returned. Data is considered corrupted in ** two circumstances: ** *** * If the record page-number is illegal (0 or PAGER_MJ_PGNO), or ** * If the record is being rolled back from the main journal file ** and the checksum field does not match the record content. *** Neither of these two scenarios are possible during a savepoint rollback. *** If this is a savepoint rollback, then memory may have to be dynamically ** allocated by this function. If this is the case and an allocation fails, ** SQLITE_NOMEM is returned.

70755. ***** Begin control #defines *****

70756. ** Two variations on the public interface for closing a database ** connection. The sqlite3_close() version returns SQLITE_BUSY and ** leaves the connection option if there are unfinalized prepared ** statements or unfinished sqlite3_backups. The sqlite3_close_v2() ** version forces the connection to become a zombie if there are ** unclosed resources, and arranges for deallocation when the last ** prepare statement or sqlite3_backup closes.

70757. ** Rtree virtual table module xCreate method.

70758. Get the results of the thread

70759. A-overwrites-T

70760. Next outer name context. NULL for outermost

70761. All cells begin balanced

70762. ** A lists of all unixInodeInfo objects.

70763. All mutexes are required for schema access. Make sure we hold them.

70764. If we are doing a reverse order scan on an ascending index, or ** a forward order scan on a descending index, interchange the ** start and end terms (pRangeStart and pRangeEnd).

70765. Page to delete cell from

70766. Page number for first page in the list

70767. Number of columns of data

70768. ** Only one of SQLITE_ENABLE_STAT3 or SQLITE_ENABLE_STAT4 can be defined. ** Priority is given to SQLITE_ENABLE_STAT4. If either are defined, also ** define SQLITE_ENABLE_STAT3_OR_STAT4

70769. Linked list of all foreign keys in this table

70770. ** pOrderBy is an ORDER BY or GROUP BY clause in SELECT statement pSelect. ** The Name context of the SELECT statement is pNC. zType is either ** "ORDER" or "GROUP" depending on which type of clause pOrderBy is. *** This routine resolves each term of the clause into an expression. ** If the order-by term is an integer I between 1 and N (where N is the ** number of columns in the result set of the SELECT) then the expression ** in the resolution is a copy of the I-th result-set expression. If ** the order-by term is an identifier that corresponds to the AS-name of ** a result-set expression, then the term resolves to a copy of the ** result-set expression. Otherwise, the expression is resolved in ** the usual way - using sqlite3ResolveExprNames(). *** This routine returns the number of errors. If errors occur, then ** an appropriate error message might be left in pParse. (OOM errors ** excepted.)

70771. ** Add code that will check to make sure the N registers starting at iMem ** form a distinct entry. iTab is a sorting index that holds previously ** seen combinations of the N values. A new entry is made in iTab ** if the current N values are new. *** A jump to addrRepeat is made and the N+1 values are popped from the ** stack if the top N elements are not distinct.

70772. Number of memory cells in the row key

70773. Profiling function

70774. ccons ::= COLLATE ID|STRING

70775. ** Move the iterator passed as the first argument to the next term in the ** segment. If successful, SQLITE_OK is returned. If there is no next term, ** SQLITE_DONE. Otherwise, an SQLite error code.

70776. Used to iterate through aTask[]

70777. ** Read the content for page pPg out of the database file and into ** pPg->pData. A shared lock or greater must be held on the database ** file before this function is called. *** If page 1 is read, then the value of Pager.dbFileVers[] is set to ** the value read from the database file. *** If an IO error occurs, then the IO error is returned to the caller. ** Otherwise, SQLITE_OK is returned.

70778. Bucket of terms object used by the integrity-check in offsets=0 mode.

70779. ** Return the number of the variable named zName, if it is in VList. ** or return 0 if there is no such variable.

70780. RHS is real

70781. ** Convert an integer into a LogEst. In other words, compute an ** approximation for $10^{\log_2(x)}$.

70782. True if a journal file is present

70783. Methods for an open file

70784. expr ::= RAISE LP IGNORE RP

70785. Index of current page in apPage

70786. ** If this is a WAL database, obtain a snapshot handle for the snapshot ** currently open. Otherwise, return an error.

70787. Form 1: Analyze everything

70788. Set stack variable q to the close-quote character

70789. Array of active savepoints

70790. True if the previous character was uEsc

70791. ** Set the sort order for the last element on the given ExprList.

70792. 380

70793. ** Indicate that registers between iReg..iReg+nReg-1 are being overwritten. ** Purge the range of registers from the column cache.

70794. Rows processed for current object

70795. when_clause ::=

70796. id value

70797. Index to read column names from

70798. tridxby ::= INDEXED BY nm

70799. ** Minimum chunk size used by streaming versions of functions.

70800. OUTPUT: True if NOT NULL constraint exists

70801. **comment:** This is a helper function for sqlite3BtreeLock(). By moving ** complex, but seldom used logic, out of sqlite3BtreeLock() and ** into this routine, we avoid unnecessary stack pointer changes ** and thus help the sqlite3BtreeLock() routine to run much faster ** in the common case.
label: code-design

70802. Number of memory locations currently allocated

70803. Initialize a lookahead iterator for each phrase. After passing the ** buffer and buffer size to the lookaside-reader init function, zero ** the phrase poslist buffer. The new poslist for the phrase (containing ** the same entries as the original with some entries removed on account ** of the NEAR constraint) is written over the original even as it is ** being read. This is safe as the entries for the new poslist are a ** subset of the old, so it is not possible for data yet to be read to ** be overwritten.

70804. List of frame objects to free on VM reset

70805. Output poslist

70806. Run the BEFORE and INSTEAD OF triggers, if there are any

70807. Number of valid entries in array aNew[]

70808. The name of the trigger

70809. ** Discard all data currently cached in the hash-tables.

70810. OUT: Visibility

70811. Used to iterate through constraint array

70812. Arguments to the format string

70813. Trace function

70814. ** Close a tokenization cursor previously opened by a call to icuOpen().

70815. sqlite3GetVdbe cannot fail: VDBE already allocated

70816. Number of usable bytes on each page

70817. ** Query the hash table for a doclist associated with term pTerm/nTerm.

70818. Free up the array of auxiliary databases

70819. ** Flush all unreferenced dirty pages to disk.

70820. OUT: Set to true if really a match

70821. Input JSON text to be parsed

70822. Next with a different name but the same hash

70823. Set nByte to the number of bytes required to store the expanded blob.

70824. True if a warning has been issued

70825. **comment:** G: New-style sqlite3_rtree_query_callback()
label: code-design

70826. ** For chunk size nChunkSize, return the number of bytes that should ** be allocated for each FileChunk structure.

70827. Opcode: CreateIndex P1 P2 * * * * Synopsis: [P2]=root iDb=P1 *** Allocate a new index in the main database file if P1==0 or in the ** auxiliary database file if P1==1 or in an attached database if ** P1>1. Write the root page number of the new table into ** register P2. *** See documentation on OP_CreateTable for additional information.

70828. Allocate a buffer in which to accumulate data

70829. All other Windows platforms expect GetProcAddress() to take ** an ANSI string regardless of the _UNICODE setting

70830. Real value used when MEM_Real is set in flags

70831. SQLITE_OMIT_HEX_INTEGER

70832. ** The journal file must be open when this routine is called. A journal ** header (JOURNAL_HDR_SZ bytes) is written into the journal file at the ** current location. *** The format for the journal header is as follows: ** - 8 bytes: Magic identifying journal format. ** - 4 bytes: Number of records in journal, or -1 no sync mode is on. ** - 4 bytes: Random number used for page hash. ** - 4 bytes: Initial database page count. ** - 4 bytes: Sector size used by the process that wrote this journal. ** - 4 bytes: Database page size. *** Followed by (JOURNAL_HDR_SZ - 28) bytes of unused space.

70833. This vtab delivers always results in "ORDER BY term ASC" order.

70897. Text encoding handled by xCmp()
70898. ** The ISAUTOVACUUM macro is used within balance_nonroot() to determine ** if the database supports auto-vacuum or not. Because it is used ** within an expression that is an argument to another macro ** (sqliteMallocRaw), it is not possible to use conditional compilation. ** So, this macro is defined instead.
70899. pPage->aData
70900. ** Each SQL function is defined by an instance of the following ** structure. For global built-in functions (ex: substr(), max(), count()) ** a pointer to this structure is held in the sqlite3BuiltinFunctions object. ** For per-connection application-defined functions, a pointer to this ** structure is held in the db->aHash hash table. *** The u.pHash field is used by the global built-ins. The u.pDestructor ** field is used by per-connection app-def functions.
70901. zKWText[] encodes 834 bytes of keyword text in 554 bytes
70902. Return value
70903. If this is an RBU vacuum operation and this is the target database, ** pretend that it has at least one page. Otherwise, SQLite will not ** check for the existance of a *.wal file. rbuVfsRead() contains ** similar logic.
70904. Always cast the getpid() return type for compatibility with ** kernel modules in VxWorks.
70905. Existing index ASCENDING
70906. Array of nLevel level objects
70907. The program counter

70908. Create a snapshot object. The content of a snapshot is opaque to ** every other subsystem, so the WAL module can put whatever it needs ** in the object.
70909. Pointer to the rbu_vfs object
70910. Function name
70911. ** The next group of routines are convenience wrappers around the ** VFS methods.
70912. ** An implementation of a min-heap. ** ** aHeap[0] is the number of elements on the heap. aHeap[1] is the ** root element. The daughter nodes of aHeap[N] are aHeap[N*2] ** and aHeap[N*2+1]. ** ** The heap property is this: Every node is less than or equal to both ** of its daughter nodes. A consequence of the heap property is that the ** root node aHeap[1] is always the minimum value currently in the heap. ** ** The btreeHeapInsert() routine inserts an unsigned 32-bit number onto ** the heap, preserving the heap property. The btreeHeapPull() routine ** removes the root element from the heap (the minimum value in the heap) ** and then moves other nodes around as necessary to preserve the heap ** property. ** ** This heap is used for cell overlap and coverage testing. Each u32 ** entry represents the span of a cell or freeblock on a btree page. ** The upper 16 bits are the index of the first byte of a range and the ** lower 16 bits are the index of the last byte of that range.
70913. First operand
70914. **comment:** ** FTS4 is really an extension for FTS3. It is enabled using the ** SQLITE_ENABLE_FTS3 macro. But to avoid confusion we also call ** the SQLITE_ENABLE_FTS4 macro to serve as an alias for SQLITE_ENABLE_FTS3.

70926. Bitvec of pages already played back
70927. Delete existing record, then do INSERT or UPDATE
70928. ***** End of complete.c *****
70929. This block deals with an obscure problem. If the last connection ** that wrote to this database was operating in persistent-journal ** mode, then the journal file may at this point actually be larger ** than Pager.journalOff bytes. If the next thing in the journal ** file happens to be a journal-header (written as part of the ** previous connection's transaction), and a crash or power-failure ** occurs after nRec is updated but before this connection writes ** anything else to the journal file (or commits/rolls back its ** transaction), then SQLite may become confused when doing the ** hot-journal rollback following recovery. It may roll back all ** of this connection's data, then proceed to rolling back the old, ** out-of-date data that follows it. Database corruption. ** ** To work around this, if the journal file does appear to contain ** a valid header following Pager.journalOff, then write a 0x00 ** byte to the start of it to prevent it from being recognized. ** ** Variable iNextHdrOffset is set to the offset at which this ** problematic header will occur, if it exists. aMagic is used ** as a temporary buffer to inspect the first couple of bytes of ** the potential journal header.
70930. Alternatively, if bExtend is true, extend the file. Do this by ** writing a single byte to the end of each (OS) page being ** allocated or extended. Technically, we need only write to the ** last page in order to extend the file. But writing to all new ** pages forces the OS to allocate them immediately, which reduces ** the chances of SIGBUS while accessing the mapped region later on.
70931. "0" digits after the decimal point but before the first ** significant digit of the number

70985. True if an error has been encountered

70986. Grab the index number and argc parameters

70987. ** Each cursor has a (possibly empty) linked list of the following objects.

70988. Set a SQLITE_TOOBIG error if no NULL

70989. !defined(SQLITE OMIT_FOREIGN_KEY)

70990. ** Interpret the given string as an auto-vacuum mode value. ** ** The following strings, "none", "full" and "incremental" are ** acceptable, as are their numeric equivalents: 0, 1 and 2 respectively.

70991. Translate from this opcode to the end

70992. ** Permitted values of the SrcList.a.jointype field

70993. Offset of journal header being read

70994. An index is used

70995. Case 2: We can directly reference a single row using an ** equality comparison against the ROWID field. Or ** we reference multiple rows using a "rowid IN (...)** construct.

70996. ** Purge the unixShmNodeList list of all entries with unixShmNode.nRef==0. ** ** This is not a VFS shared-memory method; it is a utility function called ** by VFS shared-memory methods.

70997. Default case. Handles, amongst others, "nfs". ** Test byte-range lock using fcntl(). If the call succeeds, ** assume that the file-system supports POSIX style locks.

70998. ** Generate code to do constraint checks prior to an INSERT or an UPDATE ** on table pTab. ** ** The regOldData parameter is the first register in a range that contains ** the data to be inserted or the data after the update. There will be ** pTab->nCol+1 registers in this range. The first register (the one ** that regOldData points to) will contain the new rowid, or NULL in the ** case of a WITHOUT ROWID table. The second register in the range will ** contain the content of the first table column. The third register will ** contain the content of the second table column. And so forth. ** ** The regOldData parameter is similar to regOldData except that it contains ** the data prior to an UPDATE rather than afterwards. regOldData is zero ** for an INSERT. This routine can distinguish between UPDATE and INSERT by ** checking regOldData for zero. ** ** For an UPDATE, the pkChng boolean is true if the true primary key (the ** rowid for a normal table or the PRIMARY KEY for a WITHOUT ROWID table) ** might be modified by the UPDATE. If pkChng is false, then the key of ** the iDataCur content table is guaranteed to be unchanged by the UPDATE. ** ** For an INSERT, the pkChng boolean indicates whether or not the rowid ** was explicitly specified as part of the INSERT statement. If pkChng ** is zero, it means that the either rowid is computed automatically or ** that the table is a WITHOUT ROWID table and has no rowid. On an INSERT, ** pkChng will only be true if the INSERT statement provides an integer ** value for either the rowid column or its INTEGER PRIMARY KEY alias. ** ** The code generated by this routine will store new index entries into ** registers identified by aRegIdx[]. No index entry is created for ** indices where aRegIdx[i]==0. The order of indices in aRegIdx[] is ** the same as the order of indices on the linked list of indices ** at pTab->pIndex. ** ** The caller must have already opened writeable cursors on the main ** table and all applicable indices (that is to say, all indices for which ** aRegIdx[] is not zero). iDataCur is the cursor for the main table when ** inserting or updating a rowid table, or the cursor for the PRIMARY KEY ** index when operating on a WITHOUT ROWID table. iIdxCur is the cursor ** for the first index in the pTab->pIndex list. Cursors for other indices ** are at iIdxCur+N for the N-th element of the pTab->pIndex list. ** ** This routine also generates code to check constraints. NOT NULL, ** CHECK, and UNIQUE constraints are all checked. If a constraint fails, ** then the appropriate action is performed. There are five possible ** actions: ROLLBACK, ABORT, FAIL, REPLACE, and IGNORE. ** ** Constraint type Action What Happens ** ----- ** any ROLLBACK The current transaction is rolled back and ** sqlite3_step() returns immediately with a ** return code of SQLITE_CONSTRAINT. ** ** any ABORT Back out changes from the current command ** only (do not do a complete rollback) then ** cause sqlite3_step() to return immediately ** with SQLITE_CONSTRAINT. ** ** any FAIL. Sqlite3_step() returns immediately with a ** return code of SQLITE_CONSTRAINT. The ** transaction is not rolled back and any ** changes to prior rows are retained. ** ** any IGNORE The attempt to insert or update the current ** row is skipped, without throwing an error. ** Processing continues with the next row. ** (There is an immediate jump to ignoreDest.) ** ** NOT NULL REPLACE The NULL value is replace by the default ** value for that column. If the default value ** is NULL, the action is the same as ABORT. ** ** UNIQUE REPLACE The other row that conflicts with the row ** being inserted is removed. ** ** CHECK REPLACE Illegal. The results in an exception. ** ** Which action to take is determined by the overrideError parameter. ** Or if overrideError==OE_Default, then the pParse->onError parameter ** is used. Or if pParse->onError==OE_Default then the onError value ** for the constraint is used.

70999. **comment:** ** Assert that the pointer X is aligned to an 8-byte boundary. This ** macro is used only within assert() to verify that the code gets ** all alignment restrictions correct. ** ** Except, if SQLITE_4_BYTE_ALIGNED_MALLOC is defined, then the ** underlying malloc() implementation might return us 4-byte aligned ** pointers. In that case, only verify 4-byte alignment.

71105. **comment:** ***** Posix Advisory Locking ***** POSIX advisory locks are broken by design. ANSI STD 1003.1 (1996) ** section 6.5.2.2 lines 483 through 490 specify that when a process ** sets or clears a lock, that operation overrides any prior locks set ** by the same process. It does not explicitly say so, but this implies ** that it overrides locks set by the same process using a different ** file descriptor. Consider this test case: ** ** int fd1 = open("./file1", O_RDWR|O_CREAT, 0644); ** int fd2 = open("./file2", O_RDWR|O_CREAT, 0644); ** ** Suppose ./file1 and ./file2 are really the same file (because ** one is a hard or symbolic link to the other) then if you set ** an exclusive lock on fd1, then try to get an exclusive lock ** on fd2, it works. I would have expected the second lock to ** fail since there was already a lock on the file due to fd1. ** But not so. Since both locks came from the same process, the ** second overrides the first, even though they were on different ** file descriptors opened on different file names. ** ** This means that we cannot use POSIX locks to synchronize file access ** among competing threads of the same process. POSIX locks will work fine ** to synchronize access for threads in separate processes, but not ** threads within the same process. ** ** To work around the problem, SQLite has to manage file locks internally ** on its own. Whenever a new database is opened, we have to find the ** specific inode of the database file (the inode is determined by the ** st_dev and st_ino fields of the stat structure that fstat() fills in) ** and check for locks already existing on that inode. When locks are ** created or removed, we have to look at our own internal record of the ** locks to see if another thread has previously set a lock on that same ** inode. ** ** (Aside: The use of inode numbers as unique IDs does not work on VxWorks. ** For VxWorks, we have to use the alternative unique ID system based on ** canonical filename and implemented in the previous division.) ** ** The sqlite3_file structure for POSIX is no longer just an integer file ** descriptor. It is now a structure that holds the integer file ** descriptor and a pointer to a structure that describes the internal ** locks on the corresponding inode. There is one locking structure ** per inode, so if the same inode is opened twice, both unixFile structures ** point to the same locking structure. The locking structure keeps ** a reference count (so we will know when to delete it) and a "cnt" ** field that tells us its internal lock status. cnt==0 means the ** file is unlocked. cnt==1 means the file has an exclusive lock. ** cnt>0 means there are cnt shared locks on the file. ** ** Any attempt to lock or unlock a file first checks the locking ** structure. The fcntl() system call is only invoked to set a ** POSIX lock if the internal lock structure transitions between ** a locked and an unlocked state. ** ** But wait: there are yet more problems with POSIX advisory locks. ** ** If you close a file descriptor that points to a file that has locks, ** all locks on that file that are owned by the current process are ** released. To work around this problem, each unixInodeInfo object ** maintains a count of the number of pending locks on the inode. ** When an attempt is made to close an unixFile, if there are ** other unixFile open on the same inode that are holding locks, the call ** to close() the file descriptor is deferred until all of the locks clear. ** The unixInodeInfo structure keeps a list of file descriptors that need to ** be closed and that list is walked (and cleared) when the last lock ** clears. ** ** Yet another problem: LinuxThreads do not play well with posix locks. ** ** Many older versions of linux use the LinuxThreads library which is ** not posix compliant. Under LinuxThreads, a lock created by thread ** A cannot be modified or overridden by a different thread B. ** Only thread A can modify the lock. Locking behavior is correct ** if the application uses the newer Native Posix Thread Library (NPTL) ** on linux - with NPTL a lock created by thread A can override locks ** in thread B. But there is no way to know at compile-time which ** threading library is being used. So there is no way to know at ** compile-time whether or not thread A can override locks on thread B. **

One has to do a run-time check to discover the behavior of the ** current process. *** SQLite used to support LinuxThreads. But support for LinuxThreads ** was dropped beginning with version 3.7.0. SQLite will still work with ** LinuxThreads provided that (1) there is no more than one connection ** per database file in the same process and (2) database connections ** do not move across threads.

label: code-design

71106. synopsis: iplan=r[P3] zplan='P4'

71107. ** Virtual table structure.

71108. Number of entries in array

71109. The flags parameter to sqlite3BtreeOpen can be the bitwise or of the ** following values. *** NOTE: These values must match the corresponding PAGER_ values in ** pager.h.

71110. All tables indexed by name

71111. Mark every PRIMARY KEY column as NOT NULL (except for imposter tables)

71112. ** If the cell pCell, part of page pPage contains a pointer ** to an overflow page, insert an entry into the pointer-map ** for the overflow page.

71113. Write the database source cursor number here

71114. One of TK_ALL, TK_UNION, TK_EXCEPT, TK_INTERSECT

71115. True to omit the xSync on the db file

71116. Base cost: N*3

71117. YYDEBUG

71118. First doclist

71119. Table has a primary key

71120. Mapping from ORDER BY terms to result set columns

71121. Control reaches here if the candidate path is better than the ** pTo path. Replace pTo with the candidate.

71122. This branch happens for multiple negative signs. Ex: $\{(-5)\}$

71123. Name context for container

71124. Next cursor in Fts5Cursor.pCsr list

71125. Connection holding shared memory

71126. SQLITE_OMIT_TRIGGER

71127. If the source page-size is smaller than the destination page-size, ** two extra things may need to happen: *** * The destination may need to be truncated, and ** * Data stored on the pages immediately following the ** pending-byte page in the source database may need to be ** copied into the destination database.

71128. **comment:** WAL magic value. Either this value, or the same value with the least ** significant bit also set (WAL_MAGIC | 0x00000001) is stored in 32-bit ** big-endian format in the first 4 bytes of a WAL file. *** If the LSB is set, then the checksums for each frame within the WAL ** file are calculated by treating all data as an array of 32-bit ** big-endian words. Otherwise, they are calculated by interpreting ** all data as 32-bit little-endian words.

71149. ** True if heap is nearly "full" where "full" is defined by the ** sqlite3_soft_heap_limit() setting.

71150. ***** Begin file mutex.c *****

71151. Functions used to obtain and release page references.

71152. ** Maximum number of tokens a phrase may have to be considered for the ** incremental doclists strategy.

71153. fall through

71154. First arg for xInput

71155. Open connection to the WAL file

71156. Next free slot

71157. PRAGMA index_xinfo (newer version with more rows and columns)

71158. Disable the DISTINCT optimization if SQLITE_DistinctOpt is set via ** sqlite3_test_ctrl(SQLITE_TESTCTRL_OPTIMIZATIONS,...)

71159. Map from vector field to index column

71160. True if a new wal-index header is loaded

71161. ** Virtual-table object.

71162. ** Apply the changeset passed via pChangeset/nChangeset to the main database ** attached to handle "db". Invoke the supplied conflict handler callback ** to resolve any conflicts encountered while applying the change.

71163. VFS flags returned by xOpen()

71164. If the source pager is currently in a write-transaction, return ** SQLITE_BUSY immediately.

71165. IN/OUT: Previous value written to list

71166. ** The WHERE clause processing routine has two halves. The ** first part does the start of the WHERE loop and the second ** half does the tail of the WHERE loop. An instance of ** this structure is returned by the first half and passed ** into the second half to give some continuity. ** ** An instance of this object holds the complete state of the query ** planner.

71167. ** Rowid iRowid has just been appended to the current leaf page. It is the ** first on the page. This function appends an appropriate entry to the current ** doclist-index.

71168. ** Obtain a pointer to the iPage'th page of the wal-index. The wal-index ** is broken into pages of WALINDEX_PGSZ bytes. Wal-index pages are ** numbered from zero. ** ** If this call is successful, *ppPage is set to point to the wal-index ** page and SQLITE_OK is returned. If an error (an OOM or VFS error) occurs, ** then an SQLite error code is returned and *ppPage is set to 0.

71169. Current overflow page number

71170. Index to search (from 0 to p->nIndex-1)

71171. Check that the doclist does not appear to extend past the end of the ** b-tree node. And that the final byte of the doclist is 0x00. If either ** of these statements is untrue, then the data structure is corrupt.

71172. **comment:** ** This structure is used to implement an iterator that loops through ** all frames in the WAL in database page order. Where two or more frames ** correspond to the same database page, the iterator visits only the ** frame most recently written to the WAL (in other words, the frame with ** the largest index). ** ** The internals of this structure are only accessed by: ** ** walIteratorInit() - Create a new iterator, ** walIteratorNext() - Step an iterator, ** walIteratorFree() - Free an iterator. ** ** This functionality is used by the checkpoint code (see walCheckpoint()).

label: code-design

71173. Register(s) holding the LHS values

71174. True to truncate WAL file on commit

71175. docid<=?

71176. ** Close all open savepoints. This function only manipulates fields of the ** database handle object, it does not close any savepoints that may be open ** at the b-tree/pager level.

71177. ** Skip over any TK_COLLATE operators and any unlikely() ** or likelihood() function at the root of an expression.

71178. Invoked to set output variables.

71179. Number of users of pInitMutex

71180. ** Object for iterating through the merged results of one or more segments, ** visiting each term/rowid pair in the merged data. ** ** nSeg is always a power of two greater than or equal to the number of ** segments that this object is merging data from. Both the aSeg[] and ** aFirst[] arrays are sized at nSeg entries. The aSeg[] array is padded ** with zeroed objects - these are handled as if they were iterators opened ** on empty segments. ** ** The results of comparing segments aSeg[N] and aSeg[N+1], where N is an ** even number, is stored in aFirst[(nSeg+N)/2]. The "result" of the ** comparison in this context is the index of the iterator that currently ** points to the smaller term/rowid combination. Iterators at EOF are ** considered to be greater than all other iterators. ** ** aFirst[1] contains the index in aSeg[] of the iterator that points to ** the smallest key overall. aFirst[0] is unused. ** ** poslist: ** Used by sqlite3Fts5IterPoslist() when the poslist needs to be buffered. ** There is no way to tell if this is populated or not.

71181. True if not checked out

71182. **comment:** ** This function is called whenever processing of the doclist for the ** last term on leaf page (pWriter->iBtPage) is completed. ** ** The doclist-index for that term is currently stored in-memory within the ** Fts5SegWriter.aDlidx[] array. If it is large enough, this function ** writes it out to disk. Or, if it is too small to bother with, discards ** it. ** ** Fts5SegWriter.btterm currently contains the first term on page iBtPage.

of state transitions and the C [function] that performs each: *** ** OPEN -> READER [sqlite3PagerSharedLock] ** READER -> OPEN [pager_unlock] *** **
READER -> WRITER_LOCKED [sqlite3PagerBegin] ** WRITER_LOCKED -> WRITER_CACHEMOD [pager_open_journal] ** WRITER_CACHEMOD ->
WRITER_DBMOD [syncJournal] ** WRITER_DBMOD -> WRITER_FINISHED [sqlite3PagerCommitPhaseOne] ** WRITER_*** -> READER
[page_end_transaction] *** ** WRITER_*** -> ERROR [pager_error] ** ERROR -> OPEN [pager_unlock] *** *** OPEN: *** ** The pager starts up in this
state. Nothing is guaranteed in this ** state - the file may or may not be locked and the database size is ** unknown. The database may not be read or written. **
*** ** No read or write transaction is active. *** ** Any lock, or no lock at all, may be held on the database file. *** ** The dbSize, dbOrigSize and dbFileSize variables
may not be trusted. *** ** READER: *** ** In this state all the requirements for reading the database in ** rollback (non-WAL) mode are met. Unless the pager is
(or recently ** was) in exclusive-locking mode, a user-level read transaction is ** open. The database size is known in this state. *** ** A connection running with
locking_mode=normal enters this state when ** it opens a read-transaction on the database and returns to state ** OPEN after the read-transaction is completed.
However a connection ** running in locking_mode=exclusive (including temp databases) remains in ** this state even after the read-transaction is closed. The
only way ** a locking_mode=exclusive connection can transition from READER to OPEN ** is via the ERROR state (see below). *** ** A read transaction may
be active (but a write-transaction cannot). *** ** A SHARED or greater lock is held on the database file. *** ** The dbSize variable may be trusted (even if a user-
level read ** transaction is not active). The dbOrigSize and dbFileSize variables ** may not be trusted at this point. *** ** If the database is a WAL database, then
the WAL connection is open. *** ** Even if a read-transaction is not open, it is guaranteed that ** there is no hot-journal in the file-system. *** **
WRITER_LOCKED: *** ** The pager moves to this state from READER when a write-transaction ** is first opened on the database. In WRITER_LOCKED
state, all locks ** required to start a write-transaction are held, but no actual ** modifications to the cache or database have taken place. ** ** In rollback mode, a
RESERVED or (if the transaction was opened with ** BEGIN EXCLUSIVE) EXCLUSIVE lock is obtained on the database file when ** moving to this state, but
the journal file is not written to or opened ** to in this state. If the transaction is committed or rolled back while ** in WRITER_LOCKED state, all that is required
is to unlock the database ** file. *** ** IN WAL mode, WalBeginWriteTransaction() is called to lock the log file. ** If the connection is running with
locking_mode=exclusive, an attempt ** is made to obtain an EXCLUSIVE lock on the database file. *** ** A write transaction is active. *** ** If the connection is
open in rollback-mode, a RESERVED or greater ** lock is held on the database file. *** ** If the connection is open in WAL-mode, a WAL write transaction ** is
open (i.e. sqlite3WalBeginWriteTransaction() has been successfully ** called). *** ** The dbSize, dbOrigSize and dbFileSize variables are all valid. *** ** The
contents of the pager cache have not been modified. *** ** The journal file may or may not be open. *** ** Nothing (not even the first header) has been written to the
journal. *** ** WRITER_CACHEMOD: *** ** A pager moves from WRITER_LOCKED state to this state when a page is ** first modified by the upper layer. In
rollback mode the journal file ** is opened (if it is not already open) and a header written to the ** start of it. The database file on disk has not been modified. ***

*** A write transaction is active. *** A RESERVED or greater lock is held on the database file. *** The journal file is open and the first header has been written ** to it, but the header has not been synced to disk. *** The contents of the page cache have been modified. *** WRITER_DBMOD: *** The pager transitions from WRITER_CACHEMOD into WRITER_DBMOD state ** when it modifies the contents of the database file. WAL connections ** never enter this state (since they do not modify the database file, ** just the log file). *** A write transaction is active. *** An EXCLUSIVE or greater lock is held on the database file. *** The journal file is open and the first header has been written ** and synced to disk. *** The contents of the page cache have been modified (and possibly ** written to disk). *** WRITER_FINISHED: *** It is not possible for a WAL connection to enter this state. *** A rollback-mode pager changes to WRITER_FINISHED state from WRITER_DBMOD ** state after the entire transaction has been successfully written into the ** database file. In this state the transaction may be committed simply ** by finalizing the journal file. Once in WRITER_FINISHED state, it is ** not possible to modify the database further. At this point, the upper ** layer must either commit or rollback the transaction. *** A write transaction is active. *** An EXCLUSIVE or greater lock is held on the database file. *** All writing and syncing of journal and database data has finished. ** If no error occurred, all that remains is to finalize the journal to ** commit the transaction. If an error did occur, the caller will need ** to rollback the transaction. *** ERROR: *** The ERROR state is entered when an IO or disk-full error (including ** SQLITE_IOERR_NOMEM) occurs at a point in the code that makes it ** difficult to be sure that the in-memory pager state (cache contents, ** db size etc.) are consistent with the contents of the file-system. *** Temporary pager files may enter the ERROR state, but in-memory pagers ** cannot. *** For example, if an IO error occurs while performing a rollback, ** the contents of the page-cache may be left in an inconsistent state. ** At this point it would be dangerous to change back to READER state ** (as usually happens after a rollback). Any subsequent readers might ** report database corruption (due to the inconsistent cache), and if ** they upgrade to writers, they may inadvertently corrupt the database ** file. To avoid this hazard, the pager switches into the ERROR state ** instead of READER following such an error. *** Once it has entered the ERROR state, any attempt to use the pager ** to read or write data returns an error. Eventually, once all ** outstanding transactions have been abandoned, the pager is able to ** transition back to OPEN state, discarding the contents of the ** page-cache and any other in-memory state at the same time. Everything ** is reloaded from disk (and, if necessary, hot-journal rollback performed) ** when a read-transaction is next opened on the pager (transitioning ** the pager into READER state). At that point the system has recovered ** from the error. *** Specifically, the pager jumps into the ERROR state if: *** 1. An error occurs while attempting a rollback. This happens in ** function sqlite3PagerRollback(). *** 2. An error occurs while attempting to finalize a journal file ** following a commit in function sqlite3PagerCommitPhaseTwo(). ** 3. An error occurs while attempting to write to the journal or ** database file in function pagerStress() in order to free up ** memory. *** In other cases, the error is returned to the b-tree layer. The b-tree ** layer then attempts a rollback operation. If the error condition ** persists, the pager enters the ERROR state via condition (1) above. *** Condition (3) is necessary because it can be triggered by a read-only ** statement executed within a transaction. In this case, if the error ** code were simply returned to the user, the b-tree layer would not ** automatically attempt a rollback, as it assumes that an error in a ** read-only statement cannot leave the pager in an internally inconsistent ** state. *** The Pager.errCode variable is set to something other than SQLITE_OK. ** There are one or more outstanding references to pages (after the ** last reference is dropped the pager should move back to OPEN state). *** The pager is not an in-memory pager. *** Notes: *** A pager is never in WRITER_DBMOD or WRITER_FINISHED state if the ** connection is open in WAL mode. A WAL connection is always in one ** of the first four states. *** Normally, a connection open in exclusive mode is never in PAGER_OPEN ** state. There are two exceptions: immediately after exclusive-mode has ** been turned on (and before any read or write transactions are ** executed), and when the pager is leaving the "error state". *** See also: assert_pager_state().

If an OOM error does occurs, then the prior value of pList ** that is input to this routine is automatically freed. *** If pDatabase is not null, it means that the table has an optional ** database name prefix. Like this: "database.table". The pDatabase ** points to the table name and the pTable points to the database name. ** The SrcList.a[].zName field is filled with the table name which might ** come from pTable (if pDatabase is NULL) or from pDatabase. ** SrcList.a[].zDatabase is filled with the database name from pTable, ** or with NULL if no database is specified. *** In other words, if call like this: ** ** sqlite3SrcListAppend(D,A,B,0); ** ** Then B is a table name and the database name is unspecified. If called ** like this: ** ** sqlite3SrcListAppend(D,A,B,C); ** ** Then C is the table name and B is the database name. If C is defined ** then so is B. In other words, we never have a case where: ** ** sqlite3SrcListAppend(D,A,0,C); ** ** Both pTable and pDatabase are assumed to be quoted. They are dequoted ** before being added to the SrcList.

71616. Name of the table to add to the FROM clause

71617. True to disable the incremental doclist optimization. This is controled ** by special insert command 'test-no-incr-doclist'.

71618. Extend the Fts5Structure object as required to ensure the output ** segment exists.

71619. Offset of space for 4-byte poslist size

71620. If there is no "=MODE" part of the pragma, do a query for the ** current mode

71621. Check if this phrase descends from an OR expression node. If not, ** return NULL. Otherwise, the entry that corresponds to docid ** pCsr->iPrevId may lie earlier in the doclist buffer. Or, if the ** tree that the node is part of has been marked as EOF, but the node ** itself is not EOF, then it may point to an earlier entry.

71622. **comment:** The "yyy" in the name "xxx.yyy"
label: code-design

71623. aKWOOffset[i] is the index into zKWText[] of the start of ** the text for the i-th keyword.

71624. ** A value for VdbeCursor.cacheStatus that means the cache is always invalid.

71625. Name of the file used for SHM

71626. Scan for a vowel

71627. ** Values that may be OR'd together to form the argument to the ** BTREE_HINT_FLAGS hint for sqlite3BtreeCursorHint(): *** The BTREE_BULKLOAD flag is set on index cursors when the index is going ** to be filled with content that is already in sorted order. *** The BTREE_SEEK_EQ flag is set on cursors

that will get OP_SeekGE or ** OP_SeekLE opcodes for a range search, but where the range of entries ** selected will all have the same key. In other words, the cursor will ** be used only for equality key searches. **

71628. Original value of pNew->nOut

71629. Pages per sector for pTargetFd

71630. The operand

71631. File name for write-ahead log

71632. Was sqlite3_global_recover(), but that function is deprecated

71633. __cplusplus

71634. Fix the database pointer on page iPtrPage that pointed at iDbPage so ** that it points at iFreePage. Also fix the pointer map entry for ** iPtrPage.

71635. ** This routine is called if the collation factory fails to deliver a ** collation function in the best encoding but there may be other versions ** of this collation function (for other text encodings) available. Use one ** of these instead if they exist. Avoid a UTF-8 <-> UTF-16 conversion if ** possible.

71636. Bitmap representation

71637. TK_COLUMN: cursor number of table holding column ** TK_REGISTER: register number ** TK_TRIGGER: 1 -> new, 0 -> old ** EP_Unlikely: 134217728 times likelihood ** TK_SELECT: 1st register of result vector

71638. Now that there is a read-lock on the source database, query the ** source pager for the number of pages in the database.

71639. ** Compare the values currently indicated by the two nodes as follows: ** ** res = (*p1) - (*p2) ** ** Nodes that point to values that come later in the iteration order are ** considered to be larger. Nodes at EOF are the largest of all. ** ** This means that if the iteration order is ASC, then numerically larger ** rowids are considered larger. Or if it is the default DESC, numerically ** smaller rowids are larger.

71640. 237

71641. ** Open an Fts3MultiSegReader to scan the doclist for term zTerm/nTerm. Or, ** if isPrefix is true, to scan the doclist for all terms for which ** zTerm/nTerm is a prefix. If successful, return SQLITE_OK and write ** a pointer to the new Fts3MultiSegReader to *ppSegcsr. Otherwise, return ** an SQLite error code. ** ** It is the responsibility of the caller to free this object by eventually ** passing it to fts3SegReaderCursorFree() ** ** SQLITE_OK is returned if no error occurs, otherwise an SQLite error code. ** Output parameter *ppSegcsr is set to 0 if an error occurs.

71642. Size of the header in the record

71643. Current offset in a[]

71644. Whether the function call succeeded or failed, set the output parameters ** to whatever their local counterparts contain. If an error did occur, ** this has the effect of zeroing all output parameters.

71645. Error code returned by ICU function

71646. The index type

71647. True if uses a statement journal

71648. Write the master journal data to the end of the journal file. If ** an error occurs, return the error code to the caller.

71649. The BTree

71650. Statement requested from fts3SqlStmt()

71651. Number of terms in the result set

71652. Number of new slots to add to pSrc->a[]

71653. ** Change the page number of page p to newPgno.

71654. label B:

71655. The following block stores the meta information that will be returned ** to the caller in local variables zDataType, zCollSeq, notnull, primarykey ** and autoinc. At this point there are two possibilities: ** ** 1. The specified column name was "rowid", "oid" or "_rowid_" ** and there is no explicitly declared IPK column. ** ** 2. The table is not a view and the column name identified an ** explicitly declared column. Copy meta information from *pCol.

71656. ** Interpret the given string as a locking mode value.

71657. A MATCH operator or equivalent

71658. A malloc may have failed inside of the xFunc() call. If this ** is the case, clear the mallocFailed flag and return NULL.

71659. Source b-tree file

71660. One of TK_DELETE, TK_UPDATE, TK_INSERT

71661. A record being sorted

71662. Move a page here to make room for the root-page

71663. Number of bytes to allocate for iterator

71664. OUT: Total number of pages cached

71665. Opcode: Halt P1 P2 * P4 P5 ** ** Exit immediately. All open cursors, etc are closed ** automatically. ** ** P1 is the result code returned by sqlite3_exec(), sqlite3_reset(), ** or sqlite3_finalize(). For a normal halt, this should be SQLITE_OK (0). ** For errors, it can be some other value. If P1!=0 then P2 will determine ** whether or not to rollback the current transaction. Do not rollback ** if P2==OE_Fail. Do the rollback if P2==OE_Rollback. If P2==OE_Abort, ** then back out all changes that have occurred during this execution of the ** VDBE, but do not rollback the transaction. ** ** If P4 is not null then it is an error message string. ** ** P5 is a value between 0 and 4, inclusive, that modifies the P4 string. ** ** 0: (no change) ** 1: NOT NULL constraint failed: P4 ** 2: UNIQUE constraint failed: P4 ** 3: CHECK constraint failed: P4 ** 4: FOREIGN KEY constraint failed: P4 ** ** If P5 is not zero and P4 is NULL, then everything after the ":" is ** omitted. ** ** There is an implied "Halt 0 0 0" instruction inserted at the very end of ** every program. So a jump past the last instruction of the program ** is the same as executing Halt.

71666. Hash table to query

71667. True if constraint checking is deferred till COMMIT

71668. ** Get a page from the pager and initialize it. ** ** If pCur!=0 then the page is being fetched as part of a moveToChild() ** call. Do additional sanity checking on the page in this case. ** And if the fetch fails, this routine must decrement pCur->iPage. ** ** The page is fetched as read-write unless pCur is not NULL and is ** a read-only cursor. ** ** If an error occurs, then *ppPage is undefined. It ** may remain unchanged, or it may be set to an invalid value.

71669. Create a copy of the lock path if the conch is taken

71670. ***** Begin file legacy.c *****

71671. True if the EXPLAIN flag is found on the query

71672. EVIDENCE-OF: R-06866-39125 Freeblocks are always connected in order of ** increasing offset.

71673. ** Increment the schema cookie of the main database opened by p->dbMain. ** ** Or, if this is an RBU vacuum, set the schema cookie of the main db ** opened by p->dbMain to one more than the schema cookie of the main ** db opened by p->dbRbu.

71674. ***** End of mem5.c *****

72028. Used when p4type is P4_INT64
72029. This only happens when coding check constraints
72030. Memory space from which to build Expr object
72031. ** Free the configuration object passed as the only argument.
72032. * The value used with sqlite3_win32_set_directory() to specify that * the temporary directory should be changed.
72033. Number of vector elements in comparison
72034. ** The next global variable is incremented each time the OP_Found opcode ** is executed. This is used to test whether or not the foreign key ** operation
implemented using OP_FkIsZero is working. This variable ** has no function other than to help verify the correct operation of the ** library.
72035. This expression is a "*" or a "TABLE.**" and needs to be ** expanded.
72036. If rc is not SQLITE_OK at this point, then either the malloc ** subsystem could not be initialized or the system failed to allocate ** the pInitMutex mutex. Return
an error in either case.

72037. bFullMutex
72038. Query prefix, if any
72039. Number of columns in this key
72040. If the sibling pages are not leaves, ensure that the right-child pointer ** of the right-most new sibling page is set to the value that was ** originally in the same field of the right-most old sibling page.
72041. 1410
72042. Code the trigger program into the sub-vdbe.
72043. ** A minimum allocation is an instance of the following structure. ** Larger allocations are an array of these structures where the ** size of the array is a power of 2. ** ** The size of this object must be a power of two. That fact is ** verified in memsys5Init().
72044. ** Called when a transaction completes (either by COMMIT or ROLLBACK). ** The sqlite3_blob object should be released at this point.
72045. Parsing context for error messages
72046. *****Include os_win.h in the middle of mutex_w32.c *****
72047. ** CAPI3REF: Total Number Of Rows Modified ** METHOD: sqlite3 *** ^This function returns the total number of rows inserted, modified or ** deleted by all [INSERT], [UPDATE] or [DELETE] statements completed ** since the database connection was opened, including those executed as ** part of trigger programs. ^Executing any other type of SQL statement ** does not affect the value returned by sqlite3_total_changes(). ** ** ^Changes made as part of [foreign key actions] are included in the ** count, but those made as part of REPLACE constraint resolution are ** not. ^Changes to a view that are intercepted by INSTEAD OF triggers ** are not counted. ** ** See also the [sqlite3_changes()] interface, the ** [count_changes pragma], and the [total_changes() SQL function]. ** ** If a separate thread makes changes on the same database connection ** while [sqlite3_total_changes()] is running then the value ** returned is unpredictable and not meaningful.
72048. ** Read or write a four-byte big-endian integer value.
72049. ** Return pointers to the hash table and page number array stored on ** page iHash of the wal-index. The wal-index is broken into 32KB pages ** numbered starting from 0. ** ** Set output variable *paHash to point to the start of the hash table ** in the wal-index file. Set *piZero to one less than the frame ** number of the first frame indexed by this hash table. If a ** slot in the hash table is set to N, it refers to frame number ** (*piZero+N) in the log. ** ** Finally, set *paPgno so that *paPgno[1] is the page number of the ** first frame indexed by the hash table, frame (*piZero+1).
72050. Pointer map 'page-no' entry for pDbPage
72051. Pointer to module implementation
72052. Next output slot in pColset
72053. ** Return TRUE if the word ends in a double consonant. ** ** The text is reversed here. So we are really looking at ** the first two characters of z[].
72054. Number of Journal Records
72055. Check some assumptions: ** (a) the cursor is open for writing, ** (b) there is a read/write transaction open, ** (c) the connection holds a write-lock on the table (if required), ** (d) there are no conflicting read-locks, and ** (e) the cursor points at a valid row of an intKey table.
72056. The main btree structure
72057. Now, if the table is not stored in the temp database, reload any temp ** triggers. Don't use IN(...) in case SQLITE_OMIT_SUBQUERY is defined.
72058. The database name
72059. If this is a new rowid, append the 4-byte size field for the previous ** entry, and the new rowid for this entry.
72060. The function calling context
72061. Maximum page size is 64KiB
72062. ***** The next group of routines implement the I/O methods specified ** by the sqlite3_io_methods object. *****
72063. ** Add an entry to one of the pending-terms hash tables.
72064. Return number of characters processed so far. %n
72065. Add the ON clause to the end of the WHERE clause, connected by ** an AND operator.
72066. ** 2008 August 05 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** This file implements that page cache.
72067. Existing index DESCENDING
72068. sqlite3_test_control(SQLITE_TESTCTRL_OPTIMIZATIONS, sqlite3 *db, int N) ** ** Enable or disable various optimizations for testing purposes. The ** argument N is a bitmask of optimizations to be disabled. For normal ** operation N should be 0. The idea is that a test program (like the ** SQL Logic Test or SLT test module) can run the same SQL multiple times ** with various optimizations disabled to verify that the same answer ** is obtained in every case.
72069. Malloc'd child-journal file descriptor
72070. Used to iterate through hash buckets
72071. Read the schema information out of the schema tables
72072. ** This routine identifies subexpressions in the WHERE clause where ** each subexpression is separated by the AND operator or some other ** operator specified in the op parameter. The WhereClause structure ** is filled with pointers to subexpressions. For example: ** ** WHERE a=='hello' AND coalesce(b,11)<10 AND (c+12!=d OR c==22) ** \ / \ / ** slot[0] slot[1] slot[2] ** ** The original WHERE clause in pExpr is unaltered. All this routine ** does is make slot[] entries point to substructure within pExpr. ** ** In the previous sentence and in the diagram, "slot[]" refers to ** the WhereClause.a[] array. The slot[] array grows as needed to contain ** all terms of the WHERE clause.
72073. Used to be pPager->nOvfl
72074. If it is open, sync the journal file before calling UnlockAndRollback. ** If this is not done, then an unsynced portion of the open journal ** file may be played back into the database. If a power failure occurs ** while this is happening, the database could become corrupt. ** ** If an error occurs while trying to sync the journal, shift the pager ** into the ERROR state. This causes UnlockAndRollback to unlock the ** database and close the journal file without attempting to roll it ** back or finalize it. The next database user will have to do hot-journal ** rollback before accessing the database file.
72075. TRANSACTION => nothing
72076. ** xNext() method for a node of type FTS5_TERM.
72077. X is not a subset of Y
72078. ** Return true if this is an in-memory or temp-file backed pager.
72079. Pointer to current key
72080. RECURSIVE => ID
72081. ** Return the global mutex used by this PCACHE implementation. The ** sqlite3_status() routine needs access to this mutex.
72082. ** Log an error that is an API call on a connection pointer that should ** not have been used. The "type" of connection pointer is given as the ** argument. The zType is a word like "NULL" or "closed" or "invalid".
72083. Number of extra copies of last page
72084. True if statement may modify/insert multiple rows
72085. Copy of pContext passed to s_r_g_c()
72086. ** The following routines are implementations of the MemPage.xParseCell() ** method. ** ** Parse a cell content block and fill in the CellInfo structure. ** ** btreeParseCellPtr() => table btree leaf nodes ** btreeParseCellNoPayload() => table btree internal nodes ** btreeParseCellPtrIndex() => index btree nodes ** ** There is also a wrapper function btreeParseCell() that works for ** all MemPage types and that references the cell by index rather than ** by pointer.
72087. Special case: Add leading zeros if the flag .zeropad is ** set and we are not left justified
72088. Possibly overload the function if the first argument is ** a virtual table column. ** ** For infix functions (LIKE, GLOB, REGEXP, and MATCH) use the ** second argument, not the first, as the argument to test to ** see if it is a column in a virtual table. This is done because ** the left operand of infix functions (the operand we want to ** control overloading) ends up as the second argument to the ** function. The expression "A glob B" is equivalent to ** "glob(B,A)". We want to use the A in "A glob B" to test ** for function overloading. But we use the B term in "glob(B,A)".
72089. Initial checksum value input
72090. Offset to cell content of cell being deleted
72091. A count of rows changed
72092. If there is both an upper and lower bound specified, and the ** comparisons indicate that they are close together, use the fallback ** method (assume that the scan visits 1/64 of the rows) for estimating ** the number of rows visited. Otherwise, estimate the number of rows ** using the method described in the header comment for this function.

72093. ** Destroy a bitmap object. Reclaim all memory used.
72094. Write results into this register
72095. Array of jump instruction addresses
72096. Previous docid stored in doclist
72097. Return Code
72098. Source page object
72099. Phrase object to initialize
72100. Pointer to memory from sqliteMalloc()
72101. 229
72102. An i-node
72103. ** When full-text index nodes are loaded from disk, the buffer that they ** are loaded into has the following number of bytes of padding at the end ** of it. i.e. if a full-text index node is 900 bytes in size, then a buffer ** of 920 bytes is allocated for it. *** This means that if we have a pointer into a buffer containing node data, ** it is always safe to read up to two varints from it without risking an ** overread, even if the node data is corrupted.
72104. 12
72105. ** If this is a WAL database, call sqlite3WalSnapshotRecover(). If this ** is not a WAL database, return an error.
72106. ** A smaller version of VdbeOp used for the VdbeAddOpList() function because ** it takes up less space.
72107. If this is a main database file and the file was opened using a URI ** filename, check for the "modeof" parameter. If present, interpret ** its value as a filename and try to copy the mode, uid and gid from ** that file.
72108. Results
72109. get the host ID via gethostuuid(), pHostID must point to PROXY_HOSTIDLEN ** bytes of writable memory.
72110. ** Close an rbu file.
72111. ** Load an incr-merge hint from the database. The incr-merge hint, if one ** exists, is stored in the rowid==1 row of the %_stat table. *** If successful, populate blob *pHint with the value read from the %_stat ** table and return SQLITE_OK. Otherwise, if an error occurs, return an ** SQLite error code.
72112. Check to verify that it is possible to get a read lock on all ** database schemas. The inability to get a read lock indicates that ** some other database connection is holding a write-lock, which in ** turn means that the other connection has made uncommitted changes ** to the schema. *** Were we to proceed and prepare the statement against the uncommitted ** schema changes and if those schema changes are subsequently rolled ** back and different changes are made in their place, then when this ** prepared statement goes to run the schema cookie would fail to detect ** the schema change. Disaster would follow. *** This thread is currently holding mutexes on all Btrees (because ** of the sqlite3BtreeEnterAll() in sqlite3LockAndPrepare()) so it ** is not possible for another thread to start a new schema change ** while this routine is running. Hence, we do not need to hold ** locks on the schema, we just need to make sure nobody else is ** holding them. *** Note that setting READ_UNCOMMITTED overrides most lock detection, ** but it does *not* override schema lock detection, so this all still ** works even if READ_UNCOMMITTED is set.
72113. For an index scan, make sure referenced columns are actually in ** the index.
72114. The database connection holding this btree
72115. The "Select-ID" for this loop
72116. lp ::= LP
72117. Context object for fts5ParseTokenize
72118. Strings. %s
72119. A 'table' record consists of: *** * A constant 'T' character, *** * Number of columns in said table (a varint), *** * An array of nCol bytes (sPK), *** * A null-terminated table name.
72120. If pShmNode->nRef has reached 0, then close the underlying ** shared-memory file, too
72121. ** Disable lookaside memory allocation for objects that might be ** shared across database connections.
72122. 2-byte (or larger) signed integer
72123. This can occur if there exists an index on a TEMP table which ** has the same name as another index on a permanent index. Since ** the permanent table is hidden by the TEMP table, we can also ** safely ignore the index on the permanent table.
72124. ** Argument aWalData must point to an array of WAL_SAVEPOINT_NDATA u32 ** values. This function populates the array with values required to ** "rollback" the write position of the WAL handle back to the current ** point in the event of a savepoint rollback (via WalSavepointUndo()).
72125. Each a[] describes a term of the WHERE clause
72126. EV: R-33326-45252
72127. Set the value of this object
72128. If we are unable to rollback, quit and return the error ** code. This will cause the pager to enter the error state ** so that no further harm will be done. Perhaps the next ** process to come along will be able to rollback the database.
72129. ** Convert the pStep->zTarget string into a SrcList and return a pointer ** to that SrcList. *** This routine adds a specific database name, if needed, to the target when ** forming the SrcList. This prevents a trigger in one database from ** referring to a target in another database. An exception is when the ** trigger is in TEMP in which case it can refer to any other database it ** wants.
72130. old.* and new.* values
72131. Register holding maximum rowid
72132. Re-insert the contents of any underfull nodes removed from the tree.
72133. Acquire a RESERVED lock
72134. Array of WHEN terms
72135. Phrase to merge pList/nList into
72136. IN/OUT: Previous rowid written (if any)
72137. Mask for four values above
72138. ** Change the value of a Mem to be a string or a BLOB. *** The memory management strategy depends on the value of the xDel ** parameter. If the value passed is SQLITE_TRANSIENT, then the ** string is copied into a (possibly existing) buffer managed by the ** Mem structure. Otherwise, any existing buffer is freed and the ** pointer copied. *** If the string is too large (if it exceeds the SQLITE_LIMIT_LENGTH ** size limit) then no memory allocation occurs. If the string can be ** stored without allocating memory, then it is. If a memory allocation ** is required to store the string, then value of pMem is unchanged. In ** either case, SQLITE_TOOBIG is returned.
72139. **comment:** Now that it is known how many phrases there are, allocate and zero ** the required space using malloc().
label: code-design
72140. Desired text encoding
72141. ** Recover the wal-index by reading the write-ahead log file. *** This routine first tries to establish an exclusive lock on the ** wal-index to prevent other threads/processes from doing anything ** with the WAL or wal-index while recovery is running. The ** WAL_RECOVER_LOCK is also held so that other threads will know ** that this thread is running recovery. If unable to establish ** the necessary locks, this routine returns SQLITE_BUSY.
72142. ** Code an OP_Halt due to UNIQUE or PRIMARY KEY constraint violation.
72143. Pointer to page data (for checksum)
72144. Third parameter
72145. ** Free the expression node object passed as the only argument.
72146. ** Chunk i is a free chunk that has been unlinked. Adjust its ** size parameters for check-out and return a pointer to the ** user portion of the chunk.
72147. ***** Begin file sqlite3session.h *****
72148. for the right-hand
72149. ** Each instance of this object holds a sequence of WhereLoop objects ** that implement some or all of a query plan. *** Think of each WhereLoop object as a node in a graph with arcs;** showing dependencies and costs for travelling between nodes. (That is ** not a completely accurate description because WhereLoop costs are a ** vector, not a scalar, and because dependencies are many-to-one, not ** one-to-one as are graph nodes. But it is a useful visualization aid.) ** Then a WherePath object is a path through the graph that visits some ** or all of the WhereLoop objects once. *** The "solver" works by creating the N best WherePath objects of length ** 1. Then using those as a basis to compute the N best WherePath objects ** of length 2. And so forth until the length of WherePaths equals the ** number of nodes in the FROM clause. The best (lowest cost) WherePath ** at the end is the chosen query plan.
72150. Total space in bytes required on leaf

72151. **comment:** If the client is reading or writing an index and the schema is ** not loaded, then it is too difficult to actually check to see if ** the correct locks are held.
So do not bother - just return true. ** This case does not come up very often anyhow.
label: code-design

72152. Advance at least as far as this

72153. Equality constraint on the langid column

72154. ** End of interface to code in fts5_aux.c. *****

72155. conch file host id length

72156. The pCx->pCursor will be close automatically, if it exists, by ** the call above.

72157. For sizes MX_SMALL+1 and larger

72158. SQLITE_MUTEX_W32

72159. Cursor number for ephemeral table

72160. Next character in the format string

72161. ... change the ending to this (not reversed)

72162. changeset_apply() context

72163. ** Clear the WhereLoop.u union. Leave WhereLoop.pLTerm intact.

72164. Check to see if the new index entry will be unique

72165. ** Return the numeric type for pMem, either MEM_Int or MEM_Real or both or ** none. ** ** Unlike applyNumericAffinity(), this routine does not modify pMem->flags. ** But it does set pMem->u.r and pMem->u.i appropriately.

72166. ** This function is similar to sqlite3ExprDup0, except that if pzBuffer ** is not NULL then *pzBuffer is assumed to point to a buffer large enough ** to store the copy of expression p, the copies of p->u.zToken ** (if applicable), and the copies of the p->pLeft and p->pRight expressions, ** if any. Before returning, *pzBuffer is set to the first byte past the ** portion of the buffer copied into by this function.

72167. ** If the following global variable points to a string which is the ** name of a directory, then that directory will be used to store ** temporary files. ** ** See also the "PRAGMA temp_store_directory" SQL command.

72168. The SELECT statement

72169. ** Flush the current contents of VdbeSorter.list to a new PMA, possibly ** using a background thread.

72170. Array of phrase pointers

72171. BETWEENNOTNULLLIKECASCADEDELETECASECOLLATECREATECURRENT_DATEDETACH

72172. Destructor

72173. TUNING: For simple queries, only the best path is tracked. ** For 2-way joins, the 5 best paths are followed. ** For joins of 3 or more tables, track the 10 best paths

72174. The rollback may have destroyed the pPage1->aData value. So ** call btreeGetPage() on page 1 again to make ** sure pPage1->aData is set correctly.

72175. Temporary buffer

72176. key_opt ::=

72177. A slot in pIdx->aSample[]

72178. Next in BtShared.pLock list

72179. ** Return an Expr object that refers to a memory register corresponding ** to column iCol of table pTab. ** ** regBase is the first of an array of register that contains the data ** for pTab. regBase itself holds the rowid. regBase+1 holds the first ** column. regBase+2 holds the second column, and so forth.

72180. If the schema-cookie from the database file matches the cookie ** stored with the in-memory representation of the schema, do ** not reload the schema from the database file. ** ** If virtual-tables are in use, this is not just an optimization. ** Often, v-tables store their data in other SQLite tables, which ** are queried from within xNext() and other v-table methods using ** prepared queries. If such a query is out-of-date, we do not want to ** discard the database schema, as the user code implementing the ** v-table would have to be ready for the sqlite3_vtab structure itself ** to be invalidated whenever sqlite3_step() is called from within ** a v-table method.

72181. ** If compiled with SQLITE_MUTEX_NOOP, then the no-op mutex implementation ** is used regardless of the run-time threadsafety setting.

72182. ** RBU handle. ** ** nPhaseOneStep: ** If the RBU database contains an rbu_count table, this value is set to ** a running estimate of the number of b-tree operations required to ** finish populating the *-oal file. This allows the sqlite3_bp_progress() ** API to calculate the permyriadage progress of populating the *-oal file ** using the formula: ** ** $\text{permyriadage} = (10000 * \text{nProgress}) / \text{nPhaseOneStep}$ ** ** nPhaseOneStep is initialized to the sum of: ** ** nRow * (nIndex + 1) ** ** for all source tables in the RBU database, where nRow is the number ** of rows in the source table and nIndex the number of indexes on the ** corresponding target database table. ** ** This estimate is accurate if the RBU update consists entirely of ** INSERT operations. However, it is inaccurate if: ** ** ** the RBU update contains any UPDATE operations. If the PK specified ** for an UPDATE operation does not exist in the target table, then ** no b-tree operations are required on index b-trees. Or if the ** specified PK does exist, then (nIndex*2) such operations are ** required (one delete and one insert on each index b-tree). ** ** ** the RBU update contains any DELETE operations for which the specified ** PK does not exist. In this case no operations are required on index ** b-trees. ** ** ** the RBU update contains REPLACE operations. These are similar to ** UPDATE operations. ** ** nPhaseOneStep is updated to account for the conditions above during the ** first pass of each source table. The updated nPhaseOneStep value is ** stored in the rbu_state table if the RBU update is suspended.

72183. The rowid

72184. ** The SQLITE_WITHIN(P,S,E) macro checks to see if pointer P points to ** something between S (inclusive) and E (exclusive). ** ** In other words, S is a buffer and E is a pointer to the first byte after ** the end of buffer S. This macro returns true if P points to something ** contained within the buffer S.

72185. True if RowSet.pEntry is sorted

72186. Second list to merge

72187. ** Enable or disable the extended result codes.

72188. ** Unless an "EXPLAIN QUERY PLAN" command is being processed, this function ** is a no-op. Otherwise, it adds a single row of output to the EQP result, ** where the caption is of the form: ** ** "USE TEMP B-TREE FOR xxx" ** ** where xxx is one of "DISTINCT", "ORDER BY" or "GROUP BY". Exactly which ** is determined by the zUsage argument.

72189. Write new index here

72190. The result of the merge

72191. same as TK_BITNOT, synopsis: r[P1]=~r[P1]

72192. ** Write an entry into the pointer map. ** ** This routine updates the pointer map entry for page number 'key' ** so that it maps to type 'eType' and parent page number 'pgno'. ** ** If *pRC is initially non-zero (non-SQLITE_OK) then this routine is ** a no-op. If an error occurs, the appropriate error code is written ** into *pRC.

72193. Pointer to doclist for this term

72194. **comment:** ** Finalize an iterator allocated with sqlite3changeset_start(). ** ** This function may not be called on iterators passed to a conflict handler ** callback by changeset_apply().
label: code-design

72195. It is possible to have a Blob value that has some non-zero content ** followed by zero content. But that only comes up for Blobs formed ** by the OP_MakeRecord opcode, and such Blobs never get passed into ** sqlite3MemCompare().

72196. Entries in aScan[]

72223. Required collating sequence, if not NULL

72224. ** Advance the iterator passed as an argument to the next position. Return ** 1 if the iterator is at EOF or if it now points to the start of the ** position list for the next column.

72225. (323) vtabarglist ::= vtabarg

72226. Obtain or release the WRITER lock.

72227. True (1) if h,m,s are valid

72228. 177

72229. zWal

72230. ** Generate code that will evaluate expression pExpr and store the ** results in register target. The results are guaranteed to appear ** in register target. If the expression is constant, then this routine ** might choose to code the expression at initialization time.

72231. Mask for page offset

72232. ** Add a term to the segment being constructed by the SegmentWriter object ** *ppWriter. When adding the first term to a segment, *ppWriter should ** be passed NULL. This function will allocate a new SegmentWriter object ** and return it via the input/output variable *ppWriter in this case. *** If successful, SQLITE_OK is returned. Otherwise, an SQLite error code.

72233. Number of entries in apShm[] array

72234. ***** Begin file btree.h *****

72235. Path to this element

72236. Do not require OOMs if true

72237. Put the results here

72238. **comment:** ** Transfer error message text from an sqlite3_vtab.zErrMsg (text stored ** in memory obtained from sqlite3_malloc) into a Vdbe.zErrMsg (text stored ** in memory obtained from sqlite3DbMalloc).

label: code-design

72239. ** A list of BtShared objects that are eligible for participation ** in shared cache. This variable has file scope during normal builds, ** but the test harness needs to access it so we make it global for ** test builds. *** Access to this variable is protected by SQLITE_MUTEX_STATIC_MASTER.

72240. General heap allocations

72241. ** The %_data table is completely empty when this function is called. This ** function populates it with the initial structure objects for each index, ** and the initial version of the "averages" record (a zero-byte blob).

72242. Rowset of rows to be updated

72243. Size of this object

72244. Opcode: Gt P1 P2 P3 P4 P5 ** Synopsis: IF r[P3]>r[P1] *** This works just like the Lt opcode except that the jump is taken if ** the content of register P3 is greater than the content of ** register P1. See the Lt opcode for additional information.

72245. Cannot use an IS term from the WHERE clause as an index driver for ** the RHS of a LEFT JOIN. Such a term can only be used if it is from ** the ON clause.

72246. ** Swap all content between two VDBE structures.

72247. If there has been exactly one prior match and this match ** is for the right-hand table of a NATURAL JOIN or is in a ** USING clause, then skip this match.

72248. SQLITE_CANTOPEN

72249. CLOB

72250. IEEE floating point

72251. same as TK_LE, synopsis: IF r[P3]<=r[P1]

72252. ** Initialize zType for the new view or table.

72253. Index of cursor database in db->aDb[] (or -1)

72254. 7

72255. ** Count the number of fullsyncs and normal syncs. This is used to test ** that syncs and fullsyncs are occurring at the right times.

72256. sqlite3_test_control(SQLITE_TESTCTRL_ISINIT); *** Return SQLITE_OK if SQLite has been initialized and SQLITE_ERROR if ** not.

72257. Write number of errors seen to this variable

72258. Start offset of token

72259. If the statement has been run before (and is paused at the OP_ResultRow) ** then back it up to the point where it does the OP_SeekRowid. This could ** have been down with an extra OP_Goto, but simply setting the program ** counter is faster.

72260. val now holds the lower bound of the coordinate pair

72261. ** Print the content of a WhereTerm object

72262. 1 for writing, 0 for read-only

72263. New name of table

72264. 1120

72265. True for a write lock

72266. ***** Begin file os_win.c *****

72267. Replace the backslashes from the filename and lowercase it ** to derive a mutex name.

72268. Number of elements

72269. Data for this leaf

72270. ** Provide hints to the cursor. The particular hint given (and the type ** and number of the varargs parameters) is determined by the eHintType ** parameter. See the definitions of the BTREE_HINT_* macros for details.

72271. **comment:** ** Truncate the in-memory database file image to nPage pages. This ** function does not actually modify the database file on disk. It ** just sets the internal state of the pager object so that the ** truncation will be done when the current transaction is committed. *** This function is only called right before committing a transaction. ** Once this function has been called, the transaction must either be ** rolled back or committed. It is not safe to call this function and ** then continue writing to the database.
label: code-design

72272. ** For an indexes on expression X, locate every instance of expression X in pExpr ** and change that subexpression into a reference to the appropriate column of ** the index.

72273. FTS index object

72274. Write tail of the output list here

72275. oneselect

72276. A semicolon

72277. Verify that all sibling pages are of the same "type" (table-leaf, ** table-interior, index-leaf, or index-interior).

72278. xNext - advance a cursor

72279. If the free-list must be searched for 'nearby'

72280. Destination database name

72281. ON UPDATE

72282. Buffer to accumulate new.* record in

72283. Iteration of constraint generator loop

72284. How aggressive at syncing data to disk

72285. This is the Walker callback from checkConstraintUnchanged(). Set ** bit 0x01 of pWalker->eCode if ** pWalker->eCode to 0 if this expression node references any of the ** columns that are being modified by an UPDATE statement.

72286. TBD need to come up with better match here. Perhaps ** use FILE_ID_BOTH_DIR_INFO Structure.

72287. 168

72288. ** Delete the cell at index iCell of node pNode. After removing the ** cell, adjust the r-tree data structure if required.

72289. Number of columns in one row of the result set

72290. Begin a loop that will extract all source rows in GROUP BY order. ** This might involve two separate loops with an OP_Sort in between, or ** it might be a single loop that uses an index to extract information ** in the right order to begin with.

72291. 107

72292. IN/OUT: First token of snippet

72293. synopsis: r[P3]=func(r[P2@P5])

72294. ** Test to see whether or not the database connection is in autocommit ** mode. Return TRUE if it is and FALSE if not. Autocommit mode is on ** by default. Autocommit is disabled by a BEGIN statement and reenabled ** by the next COMMIT or ROLLBACK.

72295. IMP: R-29538-34987

72296. Copy pages from the log to the database file

72297. The clause this term is part of

72298. The BLOB containing the varints

72299. Set up the array of NodeWriter objects

72300. Array of memory cells for parent frame

72301. 26

72302. *****

72303. Size of aIndex[] array

72304. ** Finish with a read transaction. All this does is release the ** read-lock.

72305. Shared part of btree structure

72306. **comment:** ** Simplify a filename into its canonical form ** by making the following changes: ** ** * removing any trailing and duplicate / ** * convert ./ into just / ** * convert /A/.. where A is any simple name into just / ** ** Changes are made in-place. Return the new name length. ** ** The original filename is in z[0..n-1]. Return the number of ** characters in the simplified name.
label: code-design

72307. Return the header size

72308. ** Return TRUE if the given operator is one of the operators that is ** allowed for an indexable WHERE clause term. The allowed operators are ** "=", "<", ">", "<=", ">=", "IN", "IS", and "IS NULL"

72309. ** Return TRUE if the iCol-th column of index pIdx is NOT NULL

72310. Address of OP_OpenEphemeral opcode for tabTnct

72311. Page p itself has already been visited.

72312. 0x10 .. 0x1F

72313. ** Attempt to set the size of the memory mapping maintained by file ** descriptor pFd to nNew bytes. Any existing mapping is discarded. ** ** If successful, this function sets the following variables: ** ** unixFile.pMapRegion ** unixFile.mmapSize ** unixFile.mmapSizeActual ** ** If unsuccessful, an error message is logged via sqlite3_log() and ** the three variables above are zeroed. In this case SQLite should ** continue accessing the database using the xRead() and xWrite() ** methods.

72314. Destructor for pPtr (or NULL)

72315. Where the SELECT should store results

72316. Iterator to advance to next page

72317. FormatMessage returns 0 on failure. Otherwise it ** returns the number of TCHARs written to the output ** buffer, excluding the terminating null char.

72318. xFetch()'d data for this page

72319. ** Implementation of the TRIM(), LTRIM(), and RTRIM() functions. ** The userdata is 0x1 for left trim, 0x2 for right trim, 0x3 for both.

72320. Set to 1 when TABLE matches

72321. ** Return a sanitized version of the sector-size of OS file pFile. The ** return value is guaranteed to lie between 32 and MAX_SECTOR_SIZE.

72322. Content registers (after the rowid)

72323. Invalid value

72324. The cookie mask contains one bit for each database file open. ** (Bit 0 is for main, bit 1 is for temp, and so forth.) Bits are ** set for each database that is used. Generate code to start a ** transaction on each used database and to verify the schema cookie ** on each used database.

72325. ** Return a pointer to static memory containing an SQL NULL value.

72326. ** Move to the next matching rowid.

72327. ** Free a snapshot handle obtained from sqlite3_snapshot_get().

72328. Index of zColumn in row-record

72329. An attempt to read a column out of a subquery or other ** temporary table.

72330. ** Set *ppModule to a pointer to the sqlite3_tokenizer_module ** structure for the unicode tokenizer.

72331. Context object for new user-function

72332. If nRowEst is zero and there is an ORDER BY clause, ignore it. In this ** case the purpose of this call is to estimate the number of rows returned ** by the overall query. Once this estimate has been obtained, the caller ** will invoke this function a second time, passing the estimate as the ** nRowEst parameter.

72333. List of other sharable Btrees from the same db

72334. **comment:** This is the first term on a leaf that is not the leftmost leaf in ** the segment b-tree. In this case it is necessary to add a term to ** the b-tree hierarchy that is (a) larger than the largest term ** already written to the segment and (b) smaller than or equal to ** this term. In other words, a prefix of (pTerm/nTerm) that is one ** byte longer than the longest prefix (pTerm/nTerm) shares with the ** previous term. ** ** Usually, the previous term is available in pPage->term. The exception ** is if this is the first term written in an incremental-merge step. ** In this case the previous term is not available, so just write a ** copy of (pTerm/nTerm) into the parent node. This is slightly ** inefficient, but still correct.
label: code-design

72335. Assign cursor numbers to the table and all its indices.

72336. Possibly relative input path

72337. List of field names to be indexed
72338. ** Convenience functions for opening and closing files using ** sqlite3_malloc() to obtain space for the file-handle structure.
72339. In this case we would like to delete the journal file. If it is ** not possible, then that is not a problem. Deleting the journal file ** here is an optimization only. **
 ** Before deleting the journal file, obtain a RESERVED lock on the ** database file. This ensures that the journal file is not deleted ** while it is in use by some other client.
72340. ** If the inner loop was generated using a non-null pOrderBy argument, ** then the results were placed in a sorter. After the loop is terminated ** we need to run the sorter and output the results. The following ** routine generates the code needed to do that.
72341. Number of PRIMARY KEY memory cells
72342. Jump here for an error that occurs after successfully allocating ** curMain and calling sqlite3BtreeEnter(). For an error that occurs ** before that point, jump to error_out.
72343. ** Return the SorterCompare function to compare values collected by the ** sorter object passed as the only argument.
72344. ** This function may only be called while the iterator is pointing to an ** SQLITE_UPDATE or SQLITE_DELETE change (see sqlite3changeset_op()). **
 Otherwise, SQLITE_MISUSE is returned. ** ** It sets *ppValue to point to an sqlite3_value structure containing the ** iVal'th value in the old.* record. Or, if that particular value is not ** included in the record (because the change is an UPDATE and the field ** was not modified and is not a PK column), set *ppValue to NULL. ** ** If value iVal is out-of-range, SQLITE_RANGE is returned and *ppValue is ** not modified. Otherwise, SQLITE_OK.
72345. 156
72346. 309
72347. SET clause for UPDATE.
72348. If this is to be the first rowid written to the page, set the ** rowid-pointer in the page-header. Also append a value to the dliidx ** buffer, in case a doclist-index is required.
72349. sqlite3AssertMayAbort() logic
72350. Size of buffer p in bytes

72404. ** Free all memory allocations in the pParse object

72405. **comment:** ** CAPI3REF: Online Backup API. ** ** The backup API copies the content of one database into another. ** It is useful either for creating backups of databases or ** for copying in-memory databases to or from persistent files. ** ** See Also: [Using the SQLite Online Backup API] ** ** ^SQLite holds a write transaction open on the destination database file ** for the duration of the backup operation. ** ^The source database is read-locked only while it is being read; ** it is not locked continuously for the entire backup operation. ** ^Thus, the backup may be performed on a live source database without ** preventing other database connections from ** reading or writing to the source database while the backup is underway. ** ** ^To perform a backup operation: ** ** sqlite3_backup_init() is called once to initialize the ** backup, ** sqlite3_backup_step() is called one or more times to transfer ** the data between the two databases, and finally ** sqlite3_backup_finish() is called to release all resources ** associated with the backup operation. ** ** There should be exactly one call to sqlite3_backup_finish() for each ** successful call to sqlite3_backup_init(). ** ** [[sqlite3_backup_init()]] sqlite3_backup_init() ** ** ^The D and N arguments to sqlite3_backup_init(D,N,S,M) are the ** [database connection] associated with the destination database ** and the database name, respectively. ** ^The database name is "main" for the main database, "temp" for the ** temporary database, or the name specified after the AS keyword in ** an [ATTACH] statement for an attached database. ** ^The S and M arguments passed to ** sqlite3_backup_init(D,N,S,M) identify the [database connection] ** and database name of the source database, respectively. ** ^The source and destination [database connections] (parameters S and D) ** must be different or else sqlite3_backup_init(D,N,S,M) will fail with ** an error. ** ** ^A call to sqlite3_backup_init() will fail, returning NULL, if ** there is already a read or read-write transaction open on the ** destination database. ** ** ^If an error occurs within sqlite3_backup_init(D,N,S,M), then NULL is ** returned and an error code and error message are stored in the ** destination [database connection] D. ** ^The error code and message for the failed call to sqlite3_backup_init() ** can be retrieved using the [sqlite3_errcode()], [sqlite3_errmsg()], and/or ** [sqlite3_errmsg16()] functions. ** ^A successful call to sqlite3_backup_init() returns a pointer to an ** [sqlite3_backup] object. ** ^The [sqlite3_backup] object may be used with the sqlite3_backup_step() and ** sqlite3_backup_finish() functions to perform the specified backup ** operation. ** ** [[sqlite3_backup_step()]] sqlite3_backup_step() ** ** ^Function sqlite3_backup_step(B,N) will copy up to N pages between ** the source and destination databases specified by [sqlite3_backup] object B. ** ^If N is negative, all remaining source pages are copied. ** ^If sqlite3_backup_step(B,N) successfully copies N pages and there ** are still more pages to be copied, then the function returns [SQLITE_OK]. ** ^If sqlite3_backup_step(B,N) successfully finishes copying all pages ** from source to destination, then it returns [SQLITE_DONE]. ** ^If an error occurs while running sqlite3_backup_step(B,N), ** then an [error code] is returned. ^As well as [SQLITE_OK] and ** [SQLITE_DONE], a call to sqlite3_backup_step() may return [SQLITE_READONLY], ** [SQLITE_NOMEM], [SQLITE_BUSY], [SQLITE_LOCKED], or an ** [SQLITE_IOERR_ACCESS | SQLITE_IOERR_XXX] extended error code. ** ** ^The sqlite3_backup_step() might return [SQLITE_READONLY] if ** ** the destination database was opened read-only, or ** the destination database is using write-ahead-log journaling ** and the destination and source page sizes differ, or ** the destination database is an in-memory database and the ** destination and source page sizes differ. ** ** ^If sqlite3_backup_step() cannot obtain a required file-system lock, then ** the [sqlite3_busy_handler | busy-handler function] ** is invoked (if one is specified). ^If the ** busy-handler returns non-zero before the lock is available, then ** [SQLITE_BUSY] is returned to the caller. ^In this case the call to ** sqlite3_backup_step() can be retried later. ^If the source ** [database connection] ** is being used to write to the source database when sqlite3_backup_step() ** is called, then [SQLITE_LOCKED] is returned immediately. ^Again, in this ** case the call to sqlite3_backup_step() can be retried later on. ^If ** [SQLITE_IOERR_ACCESS | SQLITE_IOERR_XXX], [SQLITE_NOMEM], or ** [SQLITE_READONLY] is returned, then ** there is no point in retrying the call to sqlite3_backup_step(). These ** errors are considered fatal. ^The application must accept ** that the backup operation has failed and pass the backup operation handle ** to the sqlite3_backup_finish() to release associated resources. ** ** ^The first call to sqlite3_backup_step() obtains an exclusive lock ** on the destination file. ^The exclusive lock is not released until either ** sqlite3_backup_finish() is called or the backup operation is complete ** and sqlite3_backup_step() returns [SQLITE_DONE]. ^Every call to ** sqlite3_backup_step() obtains a [shared lock] on the source database that ** lasts for the duration of the sqlite3_backup_step() call. ** ^Because the source database is not locked between calls to ** sqlite3_backup_step(), the source database may be modified mid-way ** through the backup process. ^If the source database is modified by an ** external process or via a database connection other than the one being ** used by the backup operation, then the backup will be automatically ** restarted by the next call to sqlite3_backup_step(). ^If the source ** database is modified by the using the same database connection as is used ** by the backup operation, then the backup database is automatically ** updated at the same time. ** ** [[sqlite3_backup_finish()]] sqlite3_backup_finish() ** ** ^When sqlite3_backup_step() has returned [SQLITE_DONE], or when the ** application wishes to abandon the backup operation, the application ** should destroy the [sqlite3_backup] by passing it to sqlite3_backup_finish(). ** ^The sqlite3_backup_finish() interfaces releases all ** resources associated with the [sqlite3_backup] object. ** ^If sqlite3_backup_step() has not yet returned [SQLITE_DONE], then any ** active write-transaction on the destination database is rolled back. ** The [sqlite3_backup] object is invalid ** and may not be used following a call to sqlite3_backup_finish(). ** ** ^The value returned by sqlite3_backup_finish is [SQLITE_OK] if no ** sqlite3_backup_step() errors occurred, regardless of whether or not ** sqlite3_backup_step() completed. ** ^If an out-of-memory condition or IO error occurred during any prior ** sqlite3_backup_step() call on the same [sqlite3_backup] object, then ** sqlite3_backup_finish() returns the corresponding [error code]. ** ** ^A return of [SQLITE_BUSY] or [SQLITE_LOCKED] from sqlite3_backup_step() ** is not a permanent error and does not affect the return value of ** sqlite3_backup_finish(). ** ** [[sqlite3_backup_remaining()]] [[sqlite3_backup_pagecount()]] ** sqlite3_backup_remaining() and sqlite3_backup_pagecount() ** ** ^The sqlite3_backup_remaining() routine returns the number of pages still ** to be backed up at the conclusion of the most recent sqlite3_backup_step(). ** ^The sqlite3_backup_pagecount() routine returns the total number of pages ** in the source database at the conclusion of the most recent ** sqlite3_backup_step(). ** ^The values returned by these functions are only updated by ** sqlite3_backup_step(). If the source database is modified in a way that ** changes the size of the source database or the number of pages remaining, ** those changes are not reflected in the output of sqlite3_backup_pagecount() ** and sqlite3_backup_remaining() until after the next ** sqlite3_backup_step(). ** ** ^B>Concurrent Usage of Database Handles ** ** ^The source [database connection] may be used by the application for other ** purposes while a backup operation is underway or being initialized. ** ^If SQLite is compiled and configured to support threadsafe database ** connections, then the source database connection may be used concurrently ** from within other threads. ** ** However, the application must guarantee that the destination ** [database connection] is not passed to any other API (by any thread) after ** sqlite3_backup_init() is called and before the corresponding call to ** sqlite3_backup_finish(). SQLite does not currently check to see ** if the application incorrectly accesses the destination [database connection] ** and so no error code is reported, but the operations may malfunction ** nevertheless. Use of the destination database connection while a ** backup is in progress might also cause a mutex deadlock. ** ** If running in [shared cache mode], the application must ** guarantee that the shared cache used by the destination database ** is not accessed while the backup is running. In practice this means ** that the application must guarantee that the disk file being ** backed up to is not accessed by any connection within the process, ** not just the specific connection that was passed to sqlite3_backup_init(). ** ** The [sqlite3_backup] object itself is partially threadsafe. Multiple ** threads may safely make multiple concurrent calls to sqlite3_backup_step(). ** However, the sqlite3_backup_remaining() and sqlite3_backup_pagecount() ** APIs are not strictly speaking threadsafe. If they are invoked at the ** same time as another thread is invoking sqlite3_backup_step() it is ** possible that they return invalid values.
label: code-design

72406. **comment:** ** The SQLITE_THREADSAFE macro must be defined as 0, 1, or 2. ** 0 means mutexes are permanently disable and the library is never ** threadsafe. 1 means the library is serialized which is the highest ** level of threadsafety. 2 means the library is multithreaded - multiple ** threads can use SQLite as long as no two threads try to use the same ** database connection at the same time. ** ** Older versions of SQLite used an optional THREADSAFE macro. ** We support that for legacy. ** ** To ensure that the correct value of "THREADSAFE" is reported when querying ** for compile-time options at runtime (e.g. "PRAGMA compile_options"), this ** logic is partially replicated in ctime.c. If it is updated here, it should ** also be updated there.

label: code-design

72407. Saved value of db->flags

72408. VFS to use for this b-tree

72409. Wrong number of arguments means "no match"

72410. ** Implementation of xSync() method. Flush the contents of the pending-terms ** hash-table to the database.

72411. COLUMNKW => ID

72412. **comment:** Give a better score to a function with a specific number of arguments ** than to function that accepts any number of arguments.

label: code-design

72413. Clear MemPage.isInit to make sure the corruption detection code in ** btreeInitPage() is executed.

72414. An ephemeral table

72415. Assuming the record contains N fields, the record format looks ** like this: ** *-----** | hdr-size | type 0
| type 1 | ... | type N-1 | data0 | ... | data N-1 | ** -----** Data(0) is taken from register P1. Data(1) comes from register P1+1 ** and so forth. ** ** Each type field is a varint representing the serial type of the ** corresponding data element (see sqlite3VdbeSerialType()). The ** hdr-size field is also a varint which is the offset from the beginning ** of the record to data0.

72416. WHERE clause terms

72417. ** A structure to store values read from the rbu_state table in memory.

72418. If the ORDER BY clause contains only columns in the current ** virtual table then allocate space for the aOrderBy part of ** the sqlite3_index_info structure.

72419. ** Powersafe overwrite is on by default. But can be turned off using ** the -DSQLITE_POWERSAFE_OVERWRITE=0 command-line option.

72420. True for an ephemeral table

72421. The new object must be linked on to the end of the list, not ** simply added to the start of it. This is to ensure that the ** tables within the output of sqlite3changegroup_output() are in ** the right order.

72422. Release the page reference.

72423. ** Constants for the largest and smallest possible 64-bit signed integers.

72424. SQL to be evaluated

72425. Either an error, or no such table.

72426. ** Append a new element to the given IdList. Create a new IdList if ** need be. ** ** A new IdList is returned, or NULL if malloc() fails.

72427. ** Register built-in functions used to help implement ALTER TABLE

72428. The new state to shift in

72429. WHERE clause for partial indices

72430. Name of this database. (schema name, not filename)

72431. True for select lists like "count(*)"

72432. IN/OUT: Incr. by number tokens inserted

72433. Parent tokenizer module

72434. xRead

72435. The score for this node. Smallest goes first.

72436. If the destination is DistQueue, then cursor (iParm+1) is open ** on a second ephemeral index that holds all values every previously ** added to the queue.

72437. ** Report an error that an expression is not valid for some set of ** pNC->ncFlags values determined by validMask.

72438. if exponent is present

72439. ** Determine the largest segment index value that exists within absolute ** level iAbsLevel+1. If no error occurs, set *piIdx to this value plus ** one before returning SQLITE_OK. Or, if there are no segments at all ** within level iAbsLevel, set *piIdx to zero. ** ** If an error occurs, return an SQLite error code. The final value of ** *piIdx is undefined in this case.

72440. ** Advance the cursor to the next entry in the database. ** Return value: ** ** SQLITE_OK success ** SQLITE_DONE cursor is already pointing at the last element ** otherwise some kind of error occurred ** ** The main entry point is sqlite3BtreeNext(). That routine is optimized ** for the common case of merely incrementing the cell counter BtCursor.aiIdx ** to the next cell on the current page. The (slower) btreeNext() helper ** routine is called when it is necessary to move to a different page or ** to restore the cursor. ** ** If bit 0x01 of the F argument in sqlite3BtreeNext(C,F) is 1, then the ** cursor corresponds to an SQL index and this routine could have been ** skipped if the SQL index had been a unique index. The F argument ** is a hint to the implement. SQLite btree implementation does not use ** this hint, but COMDB2 does.

72441. Function for logging

72442. Output character index

72443. We cannot be in random rowid mode if this is ** an AUTOINCREMENT table.

72444. True if src db requires unlocking

72445. Current index is unique

72446. Number of input segments

72447. ** CAPI3REF: Enable Or Disable A Session Object ** ** Enable or disable the recording of changes by a session object. When ** enabled, a session object records changes made to the database. When ** disabled - it does not. A newly created session object is enabled. ** Refer to the documentation for [sqlite3session_changeset()] for further ** details regarding how enabling and disabling a session object affects ** the eventual changesets. ** ** Passing zero to this function disables the session. Passing a value ** greater than zero enables it. Passing a value less than zero is a ** no-op, and may be used to query the current state of the session. ** ** The return value indicates the final state of the session object: 0 if ** the session is disabled, or 1 if it is enabled.

72448. ** Acquire a lock on the handle h

72449. **comment:** A memory allocation of a number of bytes which is near the maximum ** signed integer value might cause an integer overflow inside of the ** xMalloc(). Hence we limit the maximum size to 0x7fffff00, giving ** 255 bytes of overhead. SQLite itself will never use anything near ** this amount. The only way to reach the limit is with sqlite3_malloc()

label: code-design

72450. Add pPage to the dirty list

72451. ** Implementation of xOpen method.

72452. ** Arguments aLeft and aRight are pointers to change records for table pTab. ** This function returns true if the two records apply to the same row (i.e. ** have the same values stored in the primary key columns), or false ** otherwise.

72453. Final leaf to traverse

72454. The text of the modifier

72455. Initialize the node to no-match

72456. 27

72457. ** Merge two lists of pages connected by pDirty and in pgno order. ** Do not bother fixing the pDirtyPrev pointers.

72458. 29

72459. Number of references to this node

72460. 6

72461. xConnect - connect to an existing table

72462. ** Change the string value of an sqlite3_value object

72463. Set up the input stream

72464. If bCommit is zero, this loop runs exactly once and page pLastPg ** is swapped with the first free page pulled off the free list. ** ** On the other hand, if bCommit is greater than zero, then keep ** looping until a free-page located within the first nFin pages ** of the file is found.

72465. Get the exclusive locks at the system level. Then if successful ** also mark the local connection as being locked.

72466. Add this many extra columns to the end

72467. Table cursor

72468. ***** End of fts3_hash.h *****

72469. Provide the ability to easily simulate an I/O error during testing

72470. Table whose indices are to be analyzed

72471. This loop runs once for each destination page spanned by the source ** page. For each iteration, variable iOff is set to the byte offset ** of the destination page.

72472. Close any open statement handles.

72473. Set of pages moved to free-list this transaction

72474. Get the conversion type modifier

72475. 88..8f

72476. "stat" column of stat1 table

72477. e0..e7

72478. 50..57 PQRSTUVW

72479. First arg to busy callback

72480. Composite sort order

72481. 1st argument to the access auth function

72482. Max frame that can be backfilled

72483. Output operand

72484. **comment:** TODO: Check that both arguments are non-NULL
label: requirement

72485. On Android, ftruncate() always uses 32-bit offsets, even if ** _FILE_OFFSET_BITS=64 is defined. This means it is unsafe to attempt to ** truncate a file to any size larger than 2GiB. Silently ignore any ** such attempts.

72486. Buffer containing term

72487. Set iBestLvl to the level to read input segments from.

72488. Pointer to application-specific data

72489. The WHERE_* flags defined in sqliteInt.h

72490. If zName is NULL, the upper layer is requesting a temp file.

72491. ** Create a new mask for cursor iCursor. ** ** There is one cursor per table in the FROM clause. The number of ** tables in the FROM clause is limited by a test early in the ** sqlite3WhereBegin() routine. So we know that the pMaskSet->ix[] ** array will never overflow.

72492. Never called with prior errors

72493. Number of cells on this page, local and ovfl

72494. As there exists an unusable MATCH constraint this is an ** unusable plan. Set a prohibitively high cost.

72495. Information for internal btree tables

72496. 3

72497. azColumn

72498. ***** Include sqlite3ext.h in the middle of loadext.c *****

72499. vtabarg ::=

72500. Constant factoring

72501. Information desired. SQLITE_SCANSTAT_*

72502. Generate the expected index checksum based on the contents of the ** %_content table. This block stores the checksum in ctx.cksum.

72503. Open all tables in the pTabList and any indices selected for ** searching those tables.

72504. OUTPUT: True if column is auto-increment

72505. ** Attempt to allocate and return a pointer to a zeroed block of nByte ** bytes. ** ** If an error (i.e. an OOM condition) occurs, return NULL and leave an ** error code in the rbu handle passed as the first argument. Or, if an ** error has already occurred when this function is called, return NULL ** immediately without attempting the allocation or modifying the stored ** error code.

72506. 910

72507. xDisconnect

72508. Name of the database

72509. ** Read a 64-bit variable-length integer from memory starting at p[0]. ** Return the number of bytes read, or 0 on error. ** The value is stored in *v.

72510. Used internally - xBestIndex should ignore

72511. Number of leaf pages yet to be written

72512. Name of database file

72513. ** The following global variable is incremented every time a cursor ** moves, either by the OP_SeekXX, OP_Next, or OP_Prev opcodes. The test ** procedures use this information to make sure that indices are ** working correctly. This variable has no function other than to ** help verify the correct operation of the library.

72514. Register holding rowid of CREATE TABLE entry

72515. We are forced to roll back the active transaction. Before doing ** so, abort any other statements this handle currently has active.

72516. ** Register a function to be invoked when a transaction commits. ** If the invoked function returns non-zero, then the commit becomes a ** rollback.

72517. ** This function is a no-op if *pRc is other than SQLITE_OK when it is ** called. Otherwise, append a blob of data to the buffer. ** ** If an OOM condition is encountered, set *pRc to SQLITE_NOMEM before ** returning.

72518. same as TK_FLOAT, out2

72519. **comment:** ** This is the fallback stemmer used when the porter stemmer is ** inappropriate. The input word is copied into the output with ** US-ASCII case folding. If the input word is too long (more ** than 20 bytes if it contains no digits or more than 6 bytes if ** it contains digits) then word is truncated to 20 or 6 bytes ** by taking 10 or 3 bytes from the beginning and end.
label: code-design

72520. OS functions to use for IO

72521. Pointer to value 1

72522. The expression to evaluate

72523. End of [...]

72524. ** Create a new tokenizer. The values in the argv[] array are the ** arguments passed to the "tokenizer" clause of the CREATE VIRTUAL ** TABLE statement that created the fts3 table. For example, if ** the following SQL is executed: ** ** CREATE .. USING fts3(... , tokenizer <tokenizer-name> arg1 arg2) ** ** then argc is set to 2, and the argv[] array contains pointers ** to the strings "arg1" and "arg2". ** ** This method should return either SQLITE_OK (0), or an SQLite error ** code. If SQLITE_OK is returned, then *ppTokenizer should be set ** to point at the newly created tokenizer structure. The generic ** sqlite3_tokenizer.pModule variable should not be initialized by ** this callback. The caller will do so.

72525. Previous result register. No uniqueness if 0

72526. Index to read from

72527. defined(SQLITE_MUTEX_OMIT)

72528. Bytes of space to allocate at pRet

72529. SQLITE_ENABLE_CURSOR_HINTS

72530. Maximum difference in token positions

72531. ** Set the value returned by the sqlite3_last_insert_rowid() API function.

72532. ** CAPI3REF: Obtain A Composite Changeset From A Changegroup ** ** Obtain a buffer containing a changeset (or patchset) representing the ** current contents of the changegroup. If the inputs to the changegroup ** were themselves changesets, the output is a changeset. Or, if the ** inputs were patchsets, the output is also a patchset. ** ** As with the output of the sqlite3session_changeset() and ** sqlite3session_patchset() functions, all changes related to a single ** table are grouped together in the output of this function. Tables appear ** in the same order as for the very first changeset added to the changegroup. ** If the second or subsequent changesets added to the changegroup contain ** changes for tables that do not appear in the first changeset, they are ** appended onto the end of the output changeset, again in the order in ** which they are first encountered. ** ** If an error occurs, an SQLite error code is returned and the output ** variables (*pnData) and (*ppData) are set to 0. Otherwise, SQLITE_OK ** is returned and the output variables are set to the size of and a ** pointer to the output buffer, respectively. In this case it is the ** responsibility of the caller to eventually free the buffer using a ** call to sqlite3_free().

72533. If iCol is less than zero, then the expression requests the ** rowid of the sub-select or view. This expression is legal (see ** test case misc2.2.2) - it always evaluates to NULL.

72534. expr ::= expr in_op nm dbnm paren_explist

72535. Index of *output* segment in iAbsLevel+1

72536. ** Is the sqlite3ErrName() function needed in the build? Currently, ** it is needed by "mutex_w32.c" (when debugging), "os_win.c" (when ** OSTRACE is enabled), and by several "test*.c" files (which are ** compiled using SQLITE_TEST).

72537. CONFLICTCROSSCURRENT_TIMESTAMPPRIMARYDEFERREDISTINCTDROPFAIL

72538. At this point: ** iFreeBlk: First freeblock after iStart, or zero if none ** iPtr: The address of a pointer to iFreeBlk *** Check to see if iFreeBlk should be coalesced onto the end of iStart.

72539. Next free slot in %_segments

72540. ** Open the database handle and attach the RBU database as "rbu". If an ** error occurs, leave an error code and message in the RBU handle.

72541. Candidate values for BtLock.eLock

72542. If requesting a write-lock, then the Btree must have an open write ** transaction on this file. And, obviously, for this to be so there ** must be an open write transaction on the file itself.

72543. OUT: size of doclist in bytes

72544. **comment:** It used to be that sqlite3PcacheMakeClean(pPg) was called here. But ** that call was dangerous and had no detectable benefit since the cache ** is normally cleaned by sqlite3PcacheCleanAll() after rollback and so ** has been removed.

These routines accomplish ** those tasks. ** ** The sqlite3_test_control() interface calls these routines to ** control the PRNG.
72722. Allocate memory for the Pager structure, PCache object, the ** three file descriptors, the database file name and the journal ** file name. The layout in memory is as follows: ** ** Pager object (sizeof(Pager) bytes) ** PCache object (sqlite3PcacheSize() bytes) ** Database file handle (pVfs->szOsFile bytes) ** Sub-journal file handle (journalFileSize bytes) ** Main journal file handle (journalFileSize bytes) ** Database file name (nPathname+1 bytes) ** Journal file name (nPathname+8+1 bytes)
72723. Schema of the expression
72724. The VFS containing this xAccess method
72725. OUT: Array of indexes for this table
72726. Allocate a new WhereLoop to add to the end of the list
72727. ** Set *ppStmt to a statement handle that may be used to iterate through ** all rows in the %_segdir table, from oldest to newest. If successful, ** return SQLITE_OK. If an error occurs while preparing the statement, ** return an SQLite error code. ** ** There is only ever one instance of this SQL statement compiled for ** each FTS3 table. ** ** The statement returns the following columns from the %_segdir table: ** ** 0: idx ** 1: start_block ** 2: leaves_end_block ** 3: end_block ** 4: root
72728. ** CAPI3REF: Recover snapshots from a wal file ** EXPERIMENTAL ** ** If all connections disconnect from a database file but do not perform ** a checkpoint, the existing wal file is opened along with the database ** file the next time the database is opened. At this point it is only ** possible to successfully

call sqlite3_snapshot_open() to open the most ** recent snapshot of the database (the one at the head of the wal file), ** even though the wal file may contain other valid snapshots for which ** clients have sqlite3_snapshot handles. *** This function attempts to scan the wal file associated with database zDb ** of database handle db and make all valid snapshots available to ** sqlite3_snapshot_open(). It is an error if there is already a read ** transaction open on the database, or if the database is not a wal mode ** database. *** SQLITE_OK is returned if successful, or an SQLite error code otherwise.

72729. Finalize the journal file.

72730. The columns to change in the UPDATE statement

72731. ** Set the pIdxInfo->estimatedRows variable to nRow. Unless this ** extension is currently being used by a version of SQLite too old to ** support estimatedRows. In that case this function is a no-op.

72732. pNext

72733. ***** Continuing where we left off in main.c *****

72734. If no match is found, search the built-in functions. *** If the SQLITE_PreferBuiltin flag is set, then search the built-in ** functions even if a prior app-defined function was found. And give ** priority to built-in functions. *** Except, if createFlag is true, that means that we are trying to ** install a new function. Whatever FuncDef structure is returned it will ** have fields overwritten with new information appropriate for the ** new function. But the FuncDefs for built-in functions are read-only. ** So we must not search for built-ins when creating a new function.

72735. Typecast byte array

72736. Significant digits after the decimal point

72737. Mallored memory used by some conversion

72738. ** Close all cursors in the current frame.

72739. 46

72740. The soft heap limit

72741. Number of virtual tables to lock

72742. Scan visits at most 1 row

72743. Case 3.

72744. OUT: Mapped memory

72745. Memory usable by this allocator

72746. The Z in X.Y.Z cannot be NULL

72747. List of table triggers, if required

72748. ** This macro is used to calculate hash key values for data structures. In ** order to use this macro, the entire data structure must be represented ** as a series of unsigned integers. In order to calculate a hash-key value ** for a data structure represented as three such integers, the macro may ** then be used as follows: ***
int hash_key_value; ** hash_key_value = HASH_APPEND(0, <value 1>); ** hash_key_value = HASH_APPEND(hash_key_value, <value 2>); **
hash_key_value = HASH_APPEND(hash_key_value, <value 3>); *** In practice, the data structures this macro is used for are the primary ** key values of modified rows.

72749. Phrase expression

72750. ** This function may only be called while the iterator is pointing to an ** SQLITE_UPDATE or SQLITE_INSERT change (see sqlite3changeset_op()). ** Otherwise, SQLITE_MISUSE is returned. *** It sets *ppValue to point to an sqlite3_value structure containing the ** iVal'th value in the new.* record. Or, if that particular value is not ** included in the record (because the change is an UPDATE and the field ** was not modified), set *ppValue to NULL. *** If value iVal is out-of-range, SQLITE_RANGE is returned and *ppValue is ** not modified. Otherwise, SQLITE_OK.

72751. ** This routine installs a default busy handler that waits for the ** specified number of milliseconds before returning 0.

72818. IMPLEMENTATION-OF: R-34391-24921 The sqlite3_release_memory() routine ** is a no-op returning zero if SQLite is not compiled with ** SQLITE_ENABLE_MEMORY_MANAGEMENT.

72819. The SELECT statement containing the clause

72820. Pointer to right-sibling

72821. 9

72822. **comment:** ** If *pArg is initially negative then this is a query. Set *pArg to ** 1 or 0 depending on whether or not bit mask of pFile->ctrlFlags is set. *** If *pArg is 0 or 1, then clear or set the mask bit of pFile->ctrlFlags.

label: code-design

72823. ** This function is called to generate code executed when a row is deleted ** from the parent table of foreign key constraint pFKey and, if pFKey is ** deferred, when a row is inserted into the same table. When generating ** code for an SQL UPDATE operation, this function may be called twice - ** once to "delete" the old row and once to "insert" the new row. *** ** Parameter nIncr is passed -1 when inserting a row (as this may decrease ** the number of FK violations in the db) or +1 when deleting one (as this ** may increase the number of FK constraint problems). *** ** The code generated by this function scans through the rows in the child ** table that correspond to the parent table row being deleted or inserted. ** For each child row found, one of the following actions is taken: *** ** Operation | FK type | Action taken ** ----- ** DELETE immediate Increment the "immediate constraint counter". ** Or, if the ON (UPDATE|DELETE) action is RESTRICT, ** throw a "FOREIGN KEY constraint failed" exception. *** ** INSERT immediate Decrement the "immediate constraint counter". ** DELETE deferred Increment the "deferred constraint counter". ** Or, if the ON (UPDATE|DELETE) action is RESTRICT, ** throw a "FOREIGN KEY constraint failed" exception. *** ** INSERT deferred Decrement the "deferred constraint counter". ** *** These operations are identified in the comment at the top of this file ** (fkey.c) as "I.2" and "D.2".

72824. xShmLock

72825. ** Create an RBU VFS named zName that accesses the underlying file-system ** via existing VFS zParent. Or, if the zParent parameter is passed NULL, ** then the new RBU VFS uses the default system VFS to access the file-system. ** The new object is registered as a non-default VFS with SQLite before ** returning. ** ** Part of the RBU implementation uses a custom VFS object. Usually, this ** object is created and deleted automatically by RBU. *** ** The exception is for applications that also use zipvfs. In this case, ** the custom VFS must be explicitly created by the user before the RBU ** handle is opened. The RBU VFS should be installed so that the zipvfs ** VFS uses the RBU VFS, which in turn uses any other VFS layers in use ** (for example multiplexor) to access the file-system. For example, ** to assemble an RBU enabled VFS stack that uses both zipvfs and ** multiplexor (error checking omitted): *** // Create a VFS named "multiplex" (not the default). ** sqlite3_multiplex_initialize(0, 0); *** // Create an rbu VFS named "rbu" that uses multiplexor. If the ** // second argument were replaced with NULL, the "rbu" VFS would ** // access the file-system via the system default VFS, bypassing the ** // multiplexor. ** sqlite3rbu_create_vfs("rbu", "multiplex"); *** // Create a zipvfs VFS named "zipvfs" that uses rbu. ** zipvfs_create_vfs_v3("zipvfs", "rbu", 0, xCompressorAlgorithmDetector); *** // Make zipvfs the default VFS. ** sqlite3_vfs_register(sqlite3_vfs_find("zipvfs"), 1); *** Because the default VFS created above includes a RBU functionality, it ** may be used by RBU clients. Attempting to use RBU with a zipvfs VFS stack ** that does not include the RBU layer results in an error. ** ** The overhead of adding the "rbu" VFS to the system is negligible for ** non-RBU users. There is no harm in an application accessing the ** file-system via "rbu" all the time, even if it only uses RBU functionality ** occasionally.

72826. The binary record

72827. ** Rtree virtual table module xNext method.

72828. Type of token

72829. Size of buffer zPrev in bytes

72830. Name of the column.

72831. In a join with a USING clause, omit columns in the ** using clause from the table on the right.

72832. ** Convert the given register into a string if it isn't one ** already. Return non-zero if a malloc() fails.

72833. If the database supports auto-vacuum, make sure no tables contain ** references to pointer-map pages.

72834. The cell index from which to extract the ID

72835. ** The xRename method for rtree module virtual tables.

72836. Left hand side of comparison

72837. Flags

72838. ** Return the length (in bytes) of the token that begins at z[0]. ** Store the token type in *tokenType before returning.

72839. Verify property (2)

72840. Opcode: FkCounter P1 P2 * * * * Synopsis: fkctr[P1]+=P2 ** ** Increment a "constraint counter" by P2 (P2 may be negative or positive). ** If P1 is non-zero, the database constraint counter is incremented ** (deferred foreign key constraints). Otherwise, if P1 is zero, the ** statement counter is incremented (immediate foreign key constraints).

72841. The entire doclist will not fit on this leaf. The following ** loop iterates through the poslists that make up the current ** doclist.
72842. Substitute function - never called
72843. Expression to pass to authorization callback

72895. ** Construct a new expression node for a function with multiple ** arguments.
 72896. ** Details: *** The %_data table managed by this module, *** CREATE TABLE %_data(id INTEGER PRIMARY KEY, block BLOB); *** , contains the following 5 types of records. See the comments surrounding ** the FTS5_*_ROWID macros below for a description of how %_data rowids are ** assigned to each fo them. *** 1. Structure Records: *** The set of segments that make up an index - the index structure - are ** recorded in a single record within the %_data table. The record consists ** of a single 32-bit configuration cookie value followed by a list of ** SQLite varints. If the FTS table features more than one index (because ** there are one or more prefix indexes), it is guaranteed that all share ** the same cookie value. *** Immediately following the configuration cookie, the record begins with ** three varints: ** + number of levels, ** + total number of segments on all levels, ** + value of write counter. *** Then, for each level from 0 to nMax: ** + number of input segments in ongoing merge. ** + total number of segments in level. ** + for each segment from oldest to newest: ** + segment id (always > 0) ** + first leaf page number (often 1, always greater than 0) ** + final leaf page number *** 2. The Averages Record: *** A single record within the %_data table. The data is a list of varints. ** The first value is the number of rows in the index. Then, for each column ** from left to right, the total number of tokens in the column for all ** rows of the table. *** 3. Segment leaves: *** TERM/DOCLIST FORMAT: *** Most of each segment leaf is taken up by term/doclist data. The ** general format of term/doclist, starting with the first term ** on the leaf page, is: ** varint : size of first term ** blob: first term data ** doclist: first doclist ** zero-or-more { ** varint: number of bytes in common with previous term ** varint: number of bytes of new term data (nNew) ** blob: nNew bytes of new term data ** doclist: next doclist ** } *** doclist format: ** varint: first rowid ** poslist: first poslist ** zero-or-more { ** varint: rowid delta (always > 0) ** poslist: next poslist ** } *** poslist format: ** varint: size of poslist in bytes multiplied by 2, not including ** this field. Plus 1 if this entry carries the "delete" flag. ** collist: collist for column 0 ** zero-or-more { ** 0x01 byte ** varint: column number (I) ** collist: collist for column I ** } *** collist format: ** varint: first offset + 2 ** zero-or-more { ** varint: offset delta + 2 ** } *** PAGE FORMAT *** Each leaf page begins with a 4-byte header containing 2 16-bit ** unsigned integer fields in big-endian format. They are: *** ** The byte offset of the first rowid on the page, if it exists ** and occurs before the first term (otherwise 0). *** ** The byte offset of the start of the page footer. If the page ** footer is 0 bytes in size, then this field is the same as the ** size of the leaf page in bytes. *** ** The page footer consists of a single varint for each term located ** on the page. Each varint is the byte offset of the current term ** within the page, delta-compressed against the previous value. In ** other words, the first varint in the footer is the byte offset of ** the first term, the second is the byte offset of the second less that ** of the first, and so on. *** ** The term/doclist format described above is accurate if the entire ** term/doclist data fits on a single leaf page. If this is not the case, ** the format is changed in two ways: ** + if the first rowid on a page occurs before the first term, it ** is stored as a literal value: ** varint: first rowid ** + the first term on each page is stored in the same way as the ** very first term of the segment: ** varint : size of first term ** blob: first term data *** 5. Segment doclist indexes: *** Doclist indexes are themselves b-trees, however they usually consist of ** a single leaf record only. The format of each doclist index leaf page ** is: *** ** Flags byte. Bits are: ** 0x01: Clear if leaf is also the root page, otherwise set. *** ** Page number of fts index leaf page. As a varint. *** ** First rowid on page indicated by previous field. As a varint. *** ** A list of varints, one for each subsequent termless page. A ** positive delta if the termless page contains at least one rowid, ** or an 0x00 byte otherwise. *** ** Internal doclist index nodes are: *** ** Flags byte. Bits are: ** 0x01: Clear for root page, otherwise set. *** ** Page number of first child page. As a varint. *** ** Copy of first rowid on page indicated by previous field. As a varint. *** ** A list of delta-encoded varints - the first rowid on each subsequent ** child page. ***
 72897. ** json_group_obj(NAME,VALUE)*** Return a JSON object composed of all names and values in the aggregate.
 72898. True if "PRAGMA synchronous=N" has been run

In place of ** a legal notice, here is a blessing: *** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. *** ***** This file implements the default page cache implementation (the ** sqlite3_pcachef interface). It also contains part of the implementation ** of the SQLITE_CONFIG_PAGECACHE and sqlite3_release_memory() features. ** If the default page cache implementation is overridden, then neither of ** these two features are available. *** A Page cache line looks like this: *** -----

----- | database page content | PgHdr1 | MemPage | PgHdr | ** *** The database page content is up front (so that buffer overreads tend to ** flow harmlessly into the PgHdr1, MemPage, and PgHdr extensions). MemPage ** is the extension added by the btree.c module containing information such ** as the database page number and how that database page is used. PgHdr ** is added by the pcache.c layer and contains information used to keep track ** of which pages are "dirty". PgHdr1 is an extension added by this ** module (pcache1.c). The PgHdr1 header is a subclass of sqlite3_pcachef_page. ** PgHdr1 contains information needed to look up a page by its page number. ** The superclass sqlite3_pcachef_page.pBuf points to the start of the ** database page content and sqlite3_pcachef_page.pExtra points to PgHdr. ** ** The size of the extension (MemPage+PgHdr+PgHdr1) can be determined at ** runtime using sqlite3_config(SQLITE_CONFIG_PCACHE_HDRSZ, &size). The ** sizes of the extensions sum to 272 bytes on x64 for 3.8.10, but this ** size can vary according to architecture, compile-time options, and ** SQLite library version number. *** If SQLITE_PCACHE_SEPARATE_HEADER is defined, then the extension is obtained ** using a separate memory allocation from the database page content. This ** seeks to overcome the "clownshoe" problem (also called "internal ** fragmentation" in academic literature) of allocating a few bytes more ** than a power of two with the memory allocator rounding up to the next ** power of two, and leaving the rounded-up space unused. *** This module tracks pointers to PgHdr1 objects. Only pcache.c communicates ** with this module. Information is passed back and forth as PgHdr1 pointers. ** ** The pcache.c and pager.c modules deal pointers to PgHdr objects. ** The btree.c module deals with pointers to MemPage objects. *** SOURCE OF PAGE CACHE MEMORY: *** Memory for a page might come from any of three sources: *** (1) The general-purpose memory allocator - sqlite3Malloc() ** (2) Global page-cache memory provided using sqlite3_config() with ** SQLITE_CONFIG_PAGECACHE. ** (3) PCache-local bulk allocation. *** The third case is a chunk of heap memory (defaulting to 100 pages worth) ** that is allocated when the page cache is created. The size of the local ** bulk allocation can be adjusted using *** *** sqlite3_config(SQLITE_CONFIG_PAGECACHE, (void*)0, 0, N). ** ** If N is positive, then N pages worth of memory are allocated using a single ** sqlite3Malloc() call and that memory is used for the first N pages allocated. ** Or if N is negative, then -1024*N bytes of memory are allocated and used ** for as many pages as can be accommodated. *** Only one of (2) or (3) can be used. Once the memory available to (2) or ** (3) is exhausted, subsequent allocations fail over to the general-purpose ** memory allocator (1). *** Earlier versions of SQLite used only methods (1) and (2). But experiments ** show that method (3) with N==100 provides about a 5% performance boost for ** common workloads.

Otherwise, if pExpr is NULL, then SQLITE_IGNORE ** is treated as SQLITE_DENY. In this case an error is left in pParse.

73373. **comment:** ** File Locking Notes: (Mostly about windows but also some info for Unix) *** ** We cannot use LockFileEx() or UnlockFileEx() on Win95/98/ME because ** those functions are not available. So we use only LockFile() and ** UnlockFile(). *** ** LockFile() prevents not just writing but also reading by other processes. ** A SHARED_LOCK is obtained by locking a single randomly-chosen ** byte out of a specific range of bytes. The lock byte is obtained at ** random so two separate readers can probably access the file at the ** same time, unless they are unlucky and choose the same lock byte. ** An EXCLUSIVE_LOCK is obtained by locking all bytes in the range. ** There can only be one writer. A RESERVED_LOCK is obtained by locking ** a single byte of the file that is designated as the reserved lock byte. ** A PENDING_LOCK is obtained by locking a designated byte different from ** the RESERVED_LOCK byte. *** ** On WinNT/2K/XP systems, LockFileEx() and UnlockFileEx() are available, ** which means we can use reader/writer locks. When reader/writer locks ** are used, the lock is placed on the same range of bytes that is used ** for probabilistic locking in Win95/98/ME. Hence, the locking scheme ** will support two or more Win95 readers or two or more WinNT readers. ** But a single Win95 reader will lock out all WinNT readers and a single ** WinNT reader will lock out all other Win95 readers. *** ** The following #defines specify the range of bytes used for locking. ** SHARED_SIZE is the number of bytes available in the pool from which ** a random byte is selected for a shared lock. The pool of bytes for ** shared locks begins at SHARED_FIRST. *** ** The same locking strategy and ** byte ranges are used for Unix. This leaves open the possibility of having ** clients on win95, winNT, and unix all talking to the same shared file ** and all locking correctly. To do so would require that samba (or whatever ** tool is being used for file sharing) implements locks correctly between ** windows and unix. I'm guessing that isn't likely to happen, but by ** using the same locking range we are at least open to the possibility. *** ** Locking in windows is mandatory. For this reason, we cannot store ** actual data in the bytes used for locking. The pager never allocates ** the pages involved in locking therefore. SHARED_SIZE is selected so ** that all locks will fit on a single page even at the minimum page size. ** PENDING_BYTE defines the beginning of the locks. By default PENDING_BYTE ** is set high so that we don't have to allocate an unused page except ** for very large databases. But one should test the page skipping logic ** by setting PENDING_BYTE low and running the entire regression suite. *** ** Changing the value of PENDING_BYTE results in a subtly incompatible ** file format. Depending on how it is changed, you might not notice ** the incompatibility right away, even running a full regression test. ** The default location of PENDING_BYTE is the first byte past the ** 1GB boundary. **

73437. ** CAPI3REF: Evaluate An SQL Statement ** METHOD: sqlite3_stmt ** ** After a [prepared statement] has been prepared using any of ** [sqlite3_prepare_v2()], [sqlite3_prepare_v3()], [sqlite3_prepare16_v2()], ** or [sqlite3_prepare16_v3()] or one of the legacy ** interfaces [sqlite3_prepare()] or [sqlite3_prepare16()] this function ** must be called one or more times to evaluate the statement. ** ** The details of the behavior of the sqlite3_step() interface depend ** on whether the statement was prepared using the newer "vX" interfaces ** [sqlite3_prepare_v3()], [sqlite3_prepare_v2()], [sqlite3_prepare16_v3()], ** [sqlite3_prepare16_v2()] or the older legacy ** interfaces [sqlite3_prepare()] and [sqlite3_prepare16()]. The use of the ** new "vX" interface is recommended for new applications but the legacy ** interface will continue to be supported. ** ** ^In the legacy interface, the return value will be either [SQLITE_BUSY], ** [SQLITE_DONE], [SQLITE_ROW], [SQLITE_ERROR], or [SQLITE_MISUSE]. ** ^With the "v2" interface, any of the other [result codes] or ** [extended result codes] might be returned as well. ** ** ^[SQLITE_BUSY] means that the database engine was unable to acquire the ** database locks it needs to do its job. ^If the statement is a [COMMIT] ** or occurs outside of an explicit transaction, then you can retry the ** statement. If the statement is not a [COMMIT] and occurs within an ** explicit transaction then you should rollback the transaction before ** continuing. ** ** ^[SQLITE_DONE] means that the statement has finished executing ** successfully. sqlite3_step() should not be called again on this virtual ** machine without first calling [sqlite3_reset()] to reset the virtual ** machine back to its initial state. ** ** ^If the SQL statement being executed returns any data, then [SQLITE_ROW] ** is returned each time a new row of data is ready for processing by the ** caller. The values may be accessed using the [column access functions]. ** sqlite3_step() is called again to retrieve the next row of data. ** ** ^[SQLITE_ERROR] means that a run-time error (such as a constraint ** violation) has occurred. sqlite3_step() should not be called again on ** the VM. More information may be found by calling [sqlite3_errmsg()]. ** ^With the legacy interface, a more specific error code (for example, ** [SQLITE_INTERRUPT], [SQLITE_SCHEMA], [SQLITE_CORRUPT], and so forth) ** can be obtained by calling [sqlite3_reset()] on the ** [prepared statement]. ^In the "v2" interface, ** the more specific error code is returned directly by sqlite3_step(). ** ** [SQLITE_MISUSE] means that the this routine was called inappropriately. ** Perhaps it was called on a [prepared statement] that has ** already been [sqlite3_finalize | finalized] or on one that had ** previously returned [SQLITE_ERROR] or [SQLITE_DONE]. Or it could ** be the case that the same database connection is being used by two or ** more threads at the same moment in time. ** ** For all versions of SQLite up to and including 3.6.23.1, a call to ** [sqlite3_reset()] was required after sqlite3_step() returned anything ** other than [SQLITE_ROW] before any subsequent invocation of ** sqlite3_step(). Failure to reset the prepared statement using ** [sqlite3_reset()] would result in an [SQLITE_MISUSE] return from ** sqlite3_step(). But after [version 3.6.23.1] ([dateof:3.6.23.1]), ** sqlite3_step() began ** calling [sqlite3_reset()] automatically in this circumstance rather ** than returning [SQLITE_MISUSE]. This is not considered a compatibility ** break because any application that ever receives an [SQLITE_MISUSE] error ** is broken by definition. The [SQLITE_OMIT_AUTORESET] compile-time option ** can be used to restore the legacy behavior. ** ** Goofy Interface Alert: In the legacy interface, the sqlite3_step() ** API always returns a generic error code, [SQLITE_ERROR], following any ** error other than [SQLITE_BUSY] and [SQLITE_MISUSE]. You must call ** [sqlite3_reset()] or [sqlite3_finalize()] in order to find one of the ** specific [error codes] that better describes the error. ** We admit that this is a goofy design. The problem has been fixed ** with the "v2" interface. If you prepare all of your SQL statements ** using [sqlite3_prepare_v3()] or [sqlite3_prepare_v2()] ** or [sqlite3_prepare16_v2()] or [sqlite3_prepare16_v3()] instead ** of the legacy [sqlite3_prepare()] and [sqlite3_prepare16()] interfaces, ** then the more specific [error codes] are returned directly ** by sqlite3_step(). The use of the "vX" interfaces is recommended.

73438. ** pColumns and pExpr form a vector assignment which is part of the SET ** clause of an UPDATE statement. Like this: ** ** (a,b,c) = (expr1,expr2,expr3) ** Or: (a,b,c) = (SELECT x,y,z FROM ...) ** ** For each term of the vector assignment, append new entries to the ** expression list pList. In the case of a subquery on the RHS, append ** TK_SELECT_COLUMN expressions.

73439. Real value of right operand

73440. ** Generate code for a comparison operator.

73441. SQLITE_IGNORE_FLOCK_LOCK_ERRORS

73442. ** Compare two UTF-8 strings for equality where the first string is ** a GLOB or LIKE expression. Return values: ** ** SQLITE_MATCH: Match ** SQLITE_NOMATCH: No match ** SQLITE_NOWILDCARDMATCH: No match in spite of having * or % wildcards. ** ** Globbing rules: ** ** '*' Matches any sequence of zero or more characters. ** ** '?' Matches exactly one character. ** ** [...] Matches one character from the enclosed list of ** characters. ** ** [...] Matches one character not in the enclosed list. ** ** With the [...] and [...] matching, a ')' character can be included ** in the list by making it the first character after '[' or '^'. A ** range of characters can be specified using '-'. Example: ** "[a-z]" matches any single lower-case letter. To match a '-', make ** it the last character in the list. ** ** Like matching rules: ** ** '%' Matches any sequence of zero or more characters ** ** '_' Matches any one character ** ** Ee Where E is the "esc" character and c is any other ** character, including '%', '_', and esc, match exactly c. ** ** The comments within this routine usually assume glob matching. ** ** This routine is usually quick, but can be N**2 in the worst case.

73443. ** Generate code that initializes multiple registers to string or integer ** constants. The registers begin with iDest and increase consecutively. ** One register is initialized for each character in zTypes[]. For each ** "s" character in zTypes[], the register is a string if the argument is ** not NULL, or OP_Null if the value is a null pointer. For each "I" character ** in zTypes[], the register is initialized to an integer. ** ** If the input string does not end with "X" then an OP_ResultRow instruction ** is generated for the values inserted.

73444. Next entry in sorted order

73445. Pointer to buffer containing changeset

73446. Accumulate results here

73447. **comment:** ** If the third argument is non-NULL, then this function releases a ** reference obtained by an earlier call to winFetch(). The second ** argument passed to this function must be the same as the corresponding ** argument that was passed to the winFetch() invocation. ** ** Or, if the third argument is NULL, then this function is being called ** to inform the VFS layer that, according to POSIX, any existing mapping ** may now be invalid and should be unmapped.

In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** Internal interface definitions for SQLite. **

73454. ** Call this routine to record the fact that an OOM (out-of-memory) error ** has happened. This routine will set db->mallocFailed, and also ** temporarily disable the lookaside memory allocator and interrupt ** any running VDBEs.

73455. The parent key is a composite key that includes the IPK column

73456. Size of a[] in bytes

73457. ** Convert a filename from whatever the underlying operating system ** supports for filenames into UTF-8. Space to hold the result is ** obtained from malloc and must be freed by the calling function.

73458. Description of the record

73459. sqlite3CompareAffinity() only returns TEXT if one side or the ** other has no affinity and the other side is TEXT. Hence, ** the only way for cmpaff to be TEXT is for idxaff to be TEXT ** and for the term on the LHS of the IN to have no affinity.

73460. ***** Begin file icu.c *****

73461. data_version when pStruct read

73462. TermSelect object to merge into

73463. ** Initialize bulk memory to be a consistent Mem object. ** ** The minimum amount of initialization feasible is performed.

73464. ** Write an unsigned 32-bit value in big-endian format to the supplied ** buffer.

73465. ** Generate code for the REINDEX command. *** ** REINDEX -- 1 ** REINDEX <collation> -- 2 ** REINDEX ?<database>.<tablename> -- 3 ** REINDEX ?<database>.<indexname> -- 4 *** ** Form 1 causes all indices in all attached databases to be rebuilt. ** Form 2 rebuilds all indices in all databases that use the named ** collating function. Forms 3 and 4 rebuild the named index or all ** indices associated with the named table.

73466. OUT: A pointer to the prepared statement

73467. Highwater mark for nOut

73468. Name of target db index (or null)

73469. 93

73470. ** Return true if the prepared statement is guaranteed to not modify the ** database.

73471. Additional information associated with pTerm

73472. Bytes of content in a[]. Must be a multiple of 8.

73473. Extract the value into this register

73474. Create the imposter table or tables (if required).

73475. Uses the OpenEphemeral opcode

73476. **comment:** ** Interpret the given string as a safety level. Return 0 for OFF, ** 1 for ON or NORMAL, 2 for FULL, and 3 for EXTRA. Return 1 for an empty or ** unrecognized string argument. The FULL and EXTRA option is disallowed ** if the omitFull parameter is 1. *** ** Note that the values returned are one less than the values that ** should be passed into sqlite3BtreeSetSafetyLevel(). This is done ** to support legacy SQL code. The safety level used to be boolean ** and older scripts may have used numbers 0 for OFF and 1 for ON.

73477. ***** Begin file treeview.c *****

73478. funcFlags

73479. Name of function

73480. ** 2009 Oct 23 *** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** This file is part of the SQLite FTS3 extension module. Specifically, ** this file contains code to insert, update and delete rows from FTS3 ** tables. It also contains code to merge FTS3 b-tree segments. Some ** of the sub-routines used to merge segments are also used by the query ** code in fts3.c.

73481. ** Delete an entire VDBE.

73482. ** Use nodeAcquire() to obtain the leaf node containing the record with ** rowid iRowid. If successful, set *ppLeaf to point to the node and ** return SQLITE_OK. If there is no such record in the table, set ** *ppLeaf to 0 and return SQLITE_OK. If an error occurs, set *ppLeaf ** to zero and return an SQLite error code.

73483. Prevent by getAndInitPage()

73484. **comment:** ** This function is used by SQL generated to implement the ** ALTER TABLE command. The first argument is the text of a CREATE TABLE or ** CREATE INDEX command. The second is a table name. The table name in ** the CREATE TABLE or CREATE INDEX statement is replaced with the third ** argument and the result returned. Examples: *** ** sqlite_rename_table('CREATE TABLE abc(a, b, c)', 'def') ** -> 'CREATE TABLE def(a, b, c)' *** ** sqlite_rename_table('CREATE INDEX i ON abc(a)', 'def') ** -> 'CREATE INDEX i ON def(a, b, c)'

label: code-design

73485. Index of sub-iterator just advanced

73486. The caller is responsible for zeroing output parameters.

73487. Advance the pragma virtual table cursor to the next row

73488. input ::= expr

73489. ** Call sqlite3WalkExpr() for every expression in list p or until ** an abort request is seen.

73490. Column to query (or -ve for all columns)

73491. Make sure sufficient number of registers have been allocated

73492. Cannot have triggers on a virtual table. If it were possible, ** this block would have to account for hidden column.

73493. Malloc'd space (possibly) used for zTerm

73494. The vdbe must make its own copy of the column-type and other ** column specific strings, in case the schema is reset before this ** virtual machine is deleted.

73495. If this is the first frame written into the log, write the WAL ** header to the start of the WAL file. See comments at the top of ** this source file for a description of the WAL header format.

73496. ** Delete all entries in the FTS5 index.

73497. Database filenames are double-zero terminated if they are not ** URIs with parameters. Hence, they can always be passed into ** sqlite3_uri_parameter().

73498. Omit all terms smaller than this

73499. True for a root-only reader

73500. Output register from the sorter

73501. ** Register this backup object with the associated source pager for ** callbacks when pages are changed or the cache invalidated.

73502. 1020

73503. ** Add connection db to the blocked connections list. It is assumed ** that it is not already a part of the list.

73504. Do as much as possible w/o blocking

73505. Number of the rule by which to reduce

73506. Number of terms contributing to sumEq

73507. If sorting index that was created by a prior OP_OpenEphemeral ** instruction ended up not being needed, then change the OP_OpenEphemeral ** into an OP_Noop.

73508. colset ::= LCP colsetlist RCP

73509. FROM entries not usable at this level

73510. Deleting this row means the whole table is empty. In this case ** delete the contents of all three tables and throw away any ** data in the pendingTerms hash table.

73511. Used by: index_info

73512. Dest pager

73513. True for min() and max() aggregates

73514. The subquery uses a single slot of the FROM clause of the outer ** query. If the subquery has more than one element in its FROM clause, ** then expand the outer query to make space for it to hold all elements ** of the subquery. *** ** Example: *** ** SELECT * FROM tabA, (SELECT * FROM sub1, sub2), tabB; *** ** The outer query has 3 slots in its FROM clause. One slot of the ** outer query (the middle slot) is used by the subquery. The next ** block of code will expand the outer query FROM clause to 4 slots. ** The middle slot is expanded to two slots in order to make space ** for the two elements in the FROM clause of the subquery.

73515. ** Title text to insert in front of each block

73516. ** This function is equivalent to the standard isspace() function. *** ** The standard isspace() can be awkward to use safely, because although it ** is defined to accept an argument of type int, its behavior when passed ** an integer that falls outside of the range of the unsigned char type ** is undefined (and sometimes, "undefined" means segfault). This wrapper ** is defined to accept an argument of type char, and always returns 0 for ** any values that fall outside of the range of the unsigned char type (i.e. ** negative values).

73517. Encoding to use

73518. Disallow both ON and USING clauses in the same join

73519. The LIMIT clause will terminate the loop for us

73520. Arguments for the indexing scheme

73521. Jump here when done, ex: LIMIT reached

73522. Convert TK_COLUMN nodes into TK_AGG_COLUMN and make entries in ** sAggInfo for all TK_AGG_FUNCTION nodes in expressions of the ** SELECT statement.

73523. ** Return the number of times sqlite3MemMalloc() has been called.

73524. Advance to the next row to process.

73525. Resolve the GROUP BY clause. At the same time, make sure ** the GROUP BY clause does not contain aggregate functions.

73526. OUT: Set to true if call is a no-op

73527. ***** End of vtab.c *****

73528. cmd ::= BEGIN transtype trans_opt

73529. ** Disconnect all sqlite3_vtab objects that belong to database connection ** db. This is called when db is being closed.

73530. Number of columns in this table

73531. A main database has just been opened. The following block sets ** (pFd->zWal) to point to a buffer owned by SQLite that contains ** the name of the *-wal file this db connection will use. SQLite ** happens to pass a pointer to this buffer when using xAccess() ** or xOpen() to operate on the *-wal file.

73532. 126

73533. ***** Begin file printf.c *****

73535. Name we are searching for

73536. Default tokenizer module

73537. SELECT rowid, * FROM ... WHERE rowid=?

73538. Want a pending lock?

73539. PERSIST

73540. cmd ::= PRAGMA nm dbnm LP nmnum RP

73541. Number of elements in apVal

73542. Add constraints to reduce the search space on a LIKE or GLOB ** operator. ** ** A like pattern of the form "x LIKE 'aBc%'" is changed into constraints ** ** x>='ABC' AND x<'abd' AND x LIKE 'aBc%' ** ** The last character of the prefix "abc" is incremented to form the ** termination condition "abd". If case is not significant (the default ** for LIKE) then the lower-bound is made all uppercase and the upper- ** bound is made all lowercase so that the bounds also work when comparing ** BLOBS.

73543. ** Helper functions to obtain and relinquish the global mutex. The ** global mutex is used to protect the unixInodeInfo and ** vxworksFileId objects used by this file, all of which may be ** shared by multiple threads. ** ** Function unixMutexHeld() is used to assert() that the global mutex ** is held when required. This function is only used as part of assert() ** statements. e.g. ** ** unixEnterMutex() ** assert(unixMutexHeld()), ** unixEnterLeave()

73544. Current operation

73545. Copy of aPgno[] used for sorting pages

73546. Temp storage must have already been allocated

73547. There must be at least one outstanding reference to the pager if ** in ERROR state. Otherwise the pager should have already dropped ** back to OPEN state.

73548. noop

73549. Flags passed through to VFS open

73550. **comment:** Memory for registers, parameters, cursor, etc, is allocated in one or two ** passes. On the first pass, we try to reuse unused memory at the ** end of the opcode array. If we are unable to satisfy all memory ** requirements by reusing the opcode array tail, then the second ** pass will fill in the remainder using a fresh memory allocation. ** ** This two-pass approach that reuses as much memory as possible from ** the leftover memory at the end of the opcode array. This can significantly ** reduce the amount of memory held by a prepared statement.

label: code-design

73551. Special values interpreted by sqlite3SegReaderCursor()

73552. ** Find the table that is to be indexed. Return early if not found.

73553. SQLITE_OMIT_PAGER_PRAGMAS

73554. ** Store the current database page-size in bytes in p->nPgsz. ** ** If *pRc is non-zero when this function is called, it is a no-op. ** Otherwise, if an error occurs, an SQLite error code is stored in *pRc ** before returning.

73555. ** pExpr is a comparison expression, e.g. '=', '<', IN(...) etc. ** idx_affinity is the affinity of an indexed column. Return true ** if the index with affinity idx_affinity may be used to implement ** the comparison in pExpr.

73556. Fake system time in seconds since 1970.

73557. OUT: Number of bytes at *paToken

73558. If isSimpleCount() returns a pointer to a Table structure, then ** the SQL statement is of the form: ** ** SELECT count(*) FROM <tbl> ** ** where the Table structure returned represents table <tbl>. ** ** This statement is so common that it is optimized specially. The ** OP_Count instruction is executed either on the intkey table that ** contains the data for table <tbl> or on one of its indexes. It ** is better to execute the op on an index, as indexes are almost ** always spread across less pages than their corresponding tables.

73559. BETWEEN

73560. Type of lock currently held on this file

73561. Date/time functions that use 'now', and other functions like ** sqlite_version() that might change over time cannot be used ** in an index.

73562. ** CAPI3REF: Attach A Table To A Session Object ** ** If argument zTab is not NULL, then it is the name of a table to attach ** to the session object passed as the first argument. All subsequent changes ** made to the table while the session object is enabled will be recorded. See ** documentation for [sqlite3session_changeset()] for further details. ** ** Or, if argument zTab is NULL, then changes are recorded for all tables ** in the database. If additional tables are added to the database (by ** executing "CREATE TABLE" statements) after this call is made, changes for ** the new tables are also recorded. ** ** Changes can only be recorded for tables that have a PRIMARY KEY explicitly ** defined as part of their CREATE TABLE statement. It does not matter if the ** PRIMARY KEY is an "INTEGER PRIMARY KEY" (rowid alias) or not. The PRIMARY ** KEY may consist of a single column, or may be a composite key. ** ** It is not an error if the named table does not exist in the database. Nor ** is it an error if the named table does not have a PRIMARY KEY. However, ** no changes will be recorded in either of these scenarios. ** ** Changes are not recorded for individual rows that have NULL values stored ** in one or more of their PRIMARY KEY columns. ** ** SQLITE_OK is returned if the call completes without error. Or, if an error ** occurs, an SQLite error code (e.g. SQLITE_NOMEM) is returned.

73563. IN/OUT: Right hand input list

73564. Appropriate locking method

73565. ** Lower the locking level on file descriptor pFile to eFileLock. eFileLock ** must be either NO_LOCK or SHARED_LOCK. ** ** If the locking level of the file descriptor is already at or below ** the requested locking level, this routine is a no-op. ** ** If handleNFSUnlock is true, then on downgrading an EXCLUSIVE_LOCK to SHARED ** the byte range is divided into 2 parts and the first part is unlocked then ** set to a read lock, then the other part is simply unlocked. This works ** around a bug in BSD NFS lockd (also seen on MacOSX 10.3+) that fails to ** remove the write lock on a region when a read lock is set.

73566. pgoffset

73567. If obtaining a child page for a cursor, we must verify that the page is ** compatible with the root page.

73568. 90

73569. pWriter has an exclusive lock

73570. ** If pCsr->pStmt has not been prepared (i.e. if pCsr->pStmt==0), then ** compose and prepare an SQL statement of the form: ** ** "SELECT <columns> FROM %_content WHERE rowid = ?" ** ** (or the equivalent for a content=xxx table) and set pCsr->pStmt to ** it. If an error occurs, return an SQLite error code.

73571. **comment:** As this "NEAR" object is actually a single phrase that consists ** of a single term only, grab pointers into the poslist managed by the ** fts5_index.c iterator object. This is much faster than synthesizing ** a new poslist the way we have to for more complicated phrase or NEAR ** expressions.

label: code-design

73572. ** Return a list of all triggers on table pTab if there exists at least ** one trigger that must be fired when an operation of type 'op' is ** performed on the table, and, if that operation is an UPDATE, if at ** least one of the columns in pChanges is being modified.

73573. ** This function returns the space in bytes required to store the copy ** of the Expr structure and a copy of the Expr.u.zToken string (if that ** string is defined.)

73574. Never happens because JNODE_RAW is only set by json_set(), ** json_insert() and json_replace() and those routines do not ** call jsonReturn()

73575. ** Decrement the ref-count on a virtual table object. When the ref-count ** reaches zero, call the xDisconnect() method to delete the object.

73576. ** The string z[] is an text representation of a real number. ** Convert this string to a double and write it into *pResult. ** ** The string z[] is length bytes in length (bytes, not characters) and ** uses the encoding enc. The string is not necessarily zero-terminated. ** ** Return TRUE if the result is a valid real number (or integer) and FALSE ** if the string is empty or contains extraneous text. Valid numbers ** are in one of these formats: ** ** [+/-]digits[E[+-]digits] ** [+/-]digits.[digits][E[+-]digits] ** [+/-].digits[E[+-]digits] ** ** Leading and trailing whitespace is ignored for the purpose of determining ** validity. ** ** If some prefix of the input string is a valid number, this routine ** returns FALSE but it still converts the prefix and writes the result ** into *pResult.

73577. Update the global lock state and do debug tracing

73578. Return TRUE if the jsonEachCursor object has been advanced off the end ** of the JSON object

73579. **comment:** We could allocate a fresh RowSetEntry each time one is needed, but it ** is more efficient to pull a preallocated entry from the pool
label: code-design

73580. Unqualified name of the index to create

73581. Move pPage to the front of the list

73582. Index of next entry to replace

73583. ** The second argument passed to this function is the name of a PRAGMA ** setting - "page_size", "auto_vacuum", "user_version" or "application_id". ** This function executes the following on sqlite3rbu.dbRbu: *** ** "PRAGMA main.\$zPragma" *** ** where \$zPragma is the string passed as the second argument, then ** on sqlite3rbu.dbMain: *** ** "PRAGMA main.\$zPragma = \$val" *** ** where \$val is the value returned by the first PRAGMA invocation. *** ** In short, it copies the value of the specified PRAGMA setting from ** dbRbu to dbMain.

73584. ***** End of insert.c *****

73585. Maximum number of PMAs that a single MergeEngine can merge

73586. ** Change the 'auto-vacuum' property of the database. If the 'autoVacuum' ** parameter is non-zero, then auto-vacuum mode is enabled. If zero, it ** is disabled. The default value for the auto-vacuum property is ** determined by the SQLITE_DEFAULT_AUTOVACUUM macro.

73587. expr ::= BITNOT expr

73588. ** Each memory allocation looks like this: ** ----- ** | Title | backtrace pointers | MemBlockHdr |
allocation | EndGuard | ** ----- ** | The application code sees only a pointer to the allocation. We have **
to back up from the allocation pointer to find the MemBlockHdr. The ** MemBlockHdr tells us the size of the allocation and the number of ** backtrace pointers.
There is also a guard word at the end of the ** MemBlockHdr.

73663. _FTS3_TOKENIZER_H_
73664. Database filename UTF-8 encoded
73665. **comment:** ** CAPI3REF: Mutexes *** The SQLite core uses these routines for thread ** synchronization. Though they are intended for internal ** use by SQLite, code that links against SQLite is ** permitted to use any of these routines. *** The SQLite source code contains multiple implementations ** of these mutex routines. An appropriate implementation ** is selected automatically at compile-time. The following ** implementations are available in the SQLite core: *** ** SQLITE_MUTEX_PTHREADS ** SQLITE_MUTEX_W32 ** SQLITE_MUTEX_NOOP ** *** The SQLITE_MUTEX_NOOP implementation is a set of routines ** that does no real locking and is appropriate for use in ** a single-threaded application. The SQLITE_MUTEX_PTHREADS and ** SQLITE_MUTEX_W32 implementations are appropriate for use on Unix ** and Windows. *** If SQLite is compiled with the SQLITE_MUTEX_APPDEF preprocessor ** macro defined (with "-DSQLITE_MUTEX_APPDEF=1"), then no mutex ** implementation is included with the library. In this case the ** application must supply a custom mutex implementation using the ** [SQLITE_CONFIG_MUTEX] option of the sqlite3_config() function ** before calling sqlite3_initialize() or any other public sqlite3_ ** function that calls sqlite3_initialize(). *** ^The sqlite3_mutex_alloc() routine allocates a new ** mutex and returns a pointer to it. ^The sqlite3_mutex_alloc() ** routine returns NULL if it is unable to allocate the requested ** mutex. The argument to sqlite3_mutex_alloc() must one of these ** integer constants: *** ** SQLITE_MUTEX_FAST ** SQLITE_MUTEX_RECURSIVE ** SQLITE_MUTEX_STATIC_MASTER ** SQLITE_MUTEX_STATIC_MEM ** SQLITE_MUTEX_STATIC_OPEN ** SQLITE_MUTEX_STATIC_PRNG ** SQLITE_MUTEX_STATIC_LRU ** SQLITE_MUTEX_STATIC_PMEM ** SQLITE_MUTEX_STATIC_APP1 ** SQLITE_MUTEX_STATIC_APP2 ** SQLITE_MUTEX_STATIC_APP3 ** SQLITE_MUTEX_STATIC_VFS1 ** SQLITE_MUTEX_STATIC_VFS2 ** SQLITE_MUTEX_STATIC_VFS3 ** *** ^The first two constants (SQLITE_MUTEX_FAST and SQLITE_MUTEX_RECURSIVE) ** cause sqlite3_mutex_alloc() to create ** a new mutex. ^The new mutex is recursive when SQLITE_MUTEX_RECURSIVE ** is used but not necessarily so when SQLITE_MUTEX_FAST is used. ** The mutex implementation does not need to make a distinction ** between SQLITE_MUTEX_RECURSIVE and SQLITE_MUTEX_FAST if it does ** not want to. SQLite will only request a recursive mutex in ** cases where it really needs one. If a faster non-recursive mutex ** implementation is available on the host platform, the mutex subsystem ** might return such a mutex in response to SQLITE_MUTEX_FAST. *** ^The other allowed parameters to sqlite3_mutex_alloc() (anything other ** than SQLITE_MUTEX_FAST and SQLITE_MUTEX_RECURSIVE) each return ** a pointer to a static preexisting mutex. ^Nine static mutexes are ** used by the current version of SQLite. Future versions of SQLite ** may add additional static mutexes. Static mutexes are for internal ** use by SQLite only. Applications that use SQLite mutexes should ** use only the dynamic mutexes returned by SQLITE_MUTEX_FAST or ** SQLITE_MUTEX_RECURSIVE. *** ^Note that if one of the dynamic mutex parameters (SQLITE_MUTEX_FAST ** or SQLITE_MUTEX_RECURSIVE) is used then sqlite3_mutex_alloc() ** returns a different mutex on every call. ^For the static ** mutex types, the same mutex is returned on every call that has ** the same type number. *** ^The sqlite3_mutex_free() routine deallocates a previously ** allocated dynamic mutex. Attempting to deallocate a static ** mutex results in undefined behavior. *** ^The sqlite3_mutex_enter() and sqlite3_mutex_try() routines attempt ** to enter a mutex. ^If another thread is already within the mutex, ** sqlite3_mutex_enter() will block and sqlite3_mutex_try() will return ** SQLITE_BUSY. ^The sqlite3_mutex_try() interface returns [SQLITE_OK] ** upon successful entry. ^(Mutexes created using ** SQLITE_MUTEX_RECURSIVE can be entered multiple times by the same thread. ** In such cases, the ** mutex must be exited an equal number of times before another thread ** can enter.)^ If the same thread tries to enter any mutex other ** than an SQLITE_MUTEX_RECURSIVE more than once, the behavior is undefined. *** ^Some systems (for example, Windows 95) do not support the operation ** implemented by sqlite3_mutex_try(). On those systems, sqlite3_mutex_try() ** will always return SQLITE_BUSY. The SQLite core only ever uses ** sqlite3_mutex_try() as an optimization so this is acceptable ** behavior.)*** ^The sqlite3_mutex_leave() routine exits a mutex that was ** previously entered by the same thread. The behavior ** is undefined if the mutex is not currently entered by the ** calling thread or is not currently allocated. *** ^If the argument to sqlite3_mutex_enter(), sqlite3_mutex_try(), or ** sqlite3_mutex_leave() is a NULL pointer, then all three routines ** behave as no-ops. *** See also: [sqlite3_mutex_held()] and [sqlite3_mutex_noheld()].

74223. OUT: Return data in this Mem structure.
74224. In the current implementation, the rSetup value is either zero ** or the cost of building an automatic index (NlogN) and the NlogN ** is the same for compatible WhereLoops.
74225. pIdx is a UNIQUE index (or a PRIMARY KEY) and has the right number ** of columns. If each indexed column corresponds to a foreign key ** column of pFKey, then this index is a winner.
74226. OE_Rollback etc.
74227. This is likely to be an append
74228. ** Determine the current size of a file in bytes
74229. Value returned by last rbu_step() call
74230. Bytes of memory space allocated for Vdbe.aOp[]
74231. Begin generating the code that will insert the table record into ** the SQLITE_MASTER table. Note in particular that we must go ahead ** and allocate the record number for the table entry now. Before any ** PRIMARY KEY or UNIQUE keywords are parsed. Those keywords will cause ** indices to be created and the table record must come before the ** indices. Hence, the record number for the table must be allocated ** now.
74232. **comment:** ** Mark all temporary registers as being unavailable for reuse.
label: code-design
74233. Value for "idx" field
74234. IMPLEMENTATION-OF: R-44699-57140 This mode works the same way as ** SQLITE_CHECKPOINT_RESTART with the addition that it also ** truncates the log file to zero bytes just prior to a ** successful return. *** In theory, it might be safe to do this without updating the ** wal-index header in shared memory, as all subsequent reader or ** writer clients should see that the entire log file has been ** checkpointed and behave accordingly. This seems unsafe though, ** as it would leave the system in a state where the contents of ** the wal-index header do not match the contents of the ** file-system. To avoid this, update the wal-index header to ** indicate that the log file contains zero valid frames.
74235. Attach the temporary database as 'vacuum_db'. The synchronous pragma ** can be set to 'off' for this file, as it is not recovered if a crash ** occurs anyway. The integrity of the database is maintained by a ** (possibly synchronous) transaction opened on the main database before ** sqlite3BtreeCopyFile() is called. *** An optimisation would be to use a non-journalled pager. ** (Later:) I tried setting "PRAGMA vacuum_db.journal_mode=OFF" but ** that actually made the VACUUM run slower. Very little journaling ** actually occurs when doing a vacuum since the vacuum_db is initially ** empty. Only the journal header is written. Apparently it takes more ** time to parse and run the PRAGMA to turn journaling off than it does ** to write the journal header file.
74236. New array of Db pointers
74237. Append data to the wal-index. It is not necessary to lock the ** wal-index to do this as the SQLITE_SHM_WRITE lock held on the wal-index ** guarantees that there are no other writers, and no data that may ** be in use by existing readers is being overwritten.
74238. ** Implementation of the changes() SQL function. *** IMP: R-62073-11209 The changes() SQL function is a wrapper ** around the sqlite3_changes() C/C++ function and hence follows the same ** rules for counting changes.
74239. Input stream call (or NULL)
74240. ** This function is called after a transaction has been committed. It ** invokes callbacks registered with sqlite3_wal_hook() as required.
74241. File descriptor for database pTo
74242. OUT: Bytes in returned value
74243. ** Return the full pathname of the journal file.
74244. Affinity string to modify
74245. ** Generate code into the current Vdbe to evaluate the given ** expression. Attempt to store the results in register "target". ** Return the register where results are stored. *** With this routine, there is no guarantee that results will ** be stored in target. The result might be stored in some other ** register if it is convenient to do so. The calling function ** must check the return code and move the results to the desired ** register.
74246. Content
74247. This is only called if it is guaranteed that the phrase has at least ** one incremental token. In which case the bIncr flag is set.
74248. **comment:** ** CAPI3REF: Mutex Methods Object ** ** An instance of this structure defines the low-level routines ** used to allocate and use mutexes. *** Usually, the default mutex implementations provided by SQLite are ** sufficient, however the application has the option of substituting a custom ** implementation for specialized deployments or systems for which SQLite ** does not provide a suitable implementation. In this case, the application ** creates and populates an instance of this structure to pass ** to sqlite3_config() along with the [SQLITE_CONFIG_MUTEX] option. ** Additionally, an instance of this structure can be used as an ** output variable when querying the system for the current mutex ** implementation, using the [SQLITE_CONFIG_GETMUTEX] option. *** ^The xMutexInit method defined by this structure is invoked as ** part of system initialization by the sqlite3_initialize() function. ** ^The xMutexInit routine is called by SQLite exactly once for each ** effective call to [sqlite3_initialize()]. *** ^The xMutexEnd method defined by this structure is invoked as ** part of system shutdown by the sqlite3_shutdown() function. The ** implementation of this method is expected to release all outstanding ** resources obtained by the mutex methods implementation, especially ** those obtained by the xMutexInit method. ^The xMutexEnd() ** interface is invoked exactly once for each call to [sqlite3_shutdown()]. *** ^The remaining seven methods defined by this structure (xMutexAlloc, ** xMutexFree, xMutexEnter, xMutexTry, xMutexLeave, xMutexHeld and ** xMutexNoheld) implement the following interfaces (respectively): *** ** [sqlite3_mutex_alloc()] ** [sqlite3_mutex_free()] ** [sqlite3_mutex_enter()] ** [sqlite3_mutex_try()] ** [sqlite3_mutex_leave()] ** [sqlite3_mutex_held()] ** [sqlite3_mutex_noheld()] ** *** The only difference is that the public sqlite3_XXX functions enumerated ** above silently ignore any invocations that pass a NULL pointer instead ** of a valid mutex handle. The implementations of the methods defined ** by this structure are not required to handle this case, the results ** of passing a NULL pointer instead of a valid mutex handle are undefined ** (i.e. it is acceptable to

provide an implementation that segfaults if ** it is passed a NULL pointer). *** The xMutexInit() method must be threadsafe. It must be harmless to ** invoke xMutexInit() multiple times within the same process and without ** intervening calls to xMutexEnd(). Second and subsequent calls to ** xMutexInit() must be no-ops. *** xMutexInit() must not use SQLite memory allocation ([sqlite3_malloc()] ** and its associates). Similarly, xMutexAlloc() must not use SQLite memory ** allocation for a static mutex. ^However xMutexAlloc() may use SQLite ** memory allocation for a fast or recursive mutex. *** ^SQLite will invoke the xMutexEnd() method when [sqlite3_shutdown()] is ** called, but only if the prior call to xMutexInit returned SQLITE_OK. ** If xMutexInit fails in any way, it is expected to clean up after itself ** prior to returning.

74477. ** This routine is called when an INITIALLY IMMEDIATE or INITIALLY DEFERRED ** clause is seen as part of a foreign key definition. The isDeferred ** parameter is 1 for INITIALLY DEFERRED and 0 for INITIALLY IMMEDIATE. ** The behavior of the most recently created foreign key is adjusted ** accordingly.
74478. Current index in apPage[i]
74479. Array for converting from half-bytes (nybbles) into ASCII hex ** digits.
74480. ifdef SQLITE_NO_SYNC elif HAVE_FULLFSYNC
74481. Hash table key
74482. Conversion buffer
74483. Trash all content in the buffer being freed
74484. **comment:** ** CAPI3REF: Obtain Conflicting Row Values From A Changeset Iterator ** ** This function should only be used with iterator objects passed to a ** conflict-handler callback by [sqlite3changeset_apply()] with either ** [SQLITE_CHANGESET_DATA] or [SQLITE_CHANGESET_CONFLICT]. If this function ** is called on any other iterator, [SQLITE_MISUSE] is returned and *ppValue ** is set to NULL. ** ** Argument iVal must be greater than or equal to 0, and less than the number ** of columns in the table affected by the current change. Otherwise, ** [SQLITE_RANGE] is returned and *ppValue is set to NULL. ** ** If successful, this function sets *ppValue to point to a protected ** sqlite3_value object containing the iVal'th value from the ** "conflicting row" associated with the current conflict-handler callback ** and returns SQLITE_OK. ** ** If some other error occurs (e.g. an OOM condition), an SQLite error code ** is returned and *ppValue is set to NULL.
label: code-design
74485. ** Maximum pathname length (in bytes) for Win32. The MAX_PATH macro is in ** characters, so we allocate 4 bytes per character assuming worst-case of ** 4-bytes-per-character for UTF8.
74486. Set nSum to the number of distinct (iCol+1) field prefixes that ** occur in the stat4 table for this index. Set sumEq to the sum of ** the nEq values for column iCol for the same set (adding the value ** only once where there exist duplicate prefixes).
74487. pPage->nCell must be greater than zero. If this is the root-page ** the cursor would have been INVALID above and this for(;;) loop ** not run. If this is not the root-page, then the moveToChild() routine ** would have already detected db corruption. Similarly, pPage must ** be the right kind (index or table) of b-tree page. Otherwise ** a moveToChild() or moveToRoot() call would have detected corruption.
74488. Do not allow both MEMSYS5 and MEMSYS3 to be defined together. If they ** are, disable MEMSYS3
74489. **comment:** No page should ever be explicitly rolled back that is in use, except ** for page 1 which is held in use in order to keep the lock on the ** database active. However such a page may be rolled back as a result ** of an internal error resulting in an automatic call to ** sqlite3PagerRollback().
label: code-design
74490. Must be count(*)
74491. ** If this is a WAL database, store a pointer to pSnapshot. Next time a ** read transaction is opened, attempt to read from the snapshot it ** identifies. If this is not a WAL database, return an error.
74492. The parent table
74493. Coverage: it may be that this sqlite3_step() cannot fail. There ** is already a transaction open, so the prepared statement cannot ** throw an SQLITE_SCHEMA exception. The only database page the ** statement reads is page 1, which is guaranteed to be in the cache. ** And no memory allocations are required.
74494. Bit Field Type
74495. Bytes to append to the prefix
74496. ** CAPI3REF: Move a BLOB Handle to a New Row ** METHOD: sqlite3_blob ** ** ^This function is used to move an existing [BLOB handle] so that it points ** to a different row of the same database table. ^The new row is identified ** by the rowid value passed as the second argument. Only the row can be ** changed. ^The database, table and column on which the blob handle is open ** remain the same. Moving an existing [BLOB handle] to a new row is ** faster than closing the existing handle and opening a new one. ** ** ^The new row must meet the same criteria as for [sqlite3_blob_open()] - ** it must exist and there must be either a blob or text value stored in ** the nominated column.^ ^If the new row is not present in the table, or if ** it does not contain a blob or text value, or if another error occurs, an ** SQLite error code is returned and the blob handle is considered aborted. ** ^All subsequent calls to [sqlite3_blob_read()], [sqlite3_blob_write()] or ** [sqlite3_blob_reopen()] on an aborted blob handle immediately return ** SQLITE_ABORT. ^Calling [sqlite3_blob_bytes()] on an aborted blob handle ** always returns zero. ** ** ^This function sets the database handle error code and message.
74497. **comment:** This helper routine to saveAllCursors does the actual work of saving ** the cursors if and when a cursor is found that actually requires saving. ** The common case is that no cursors need to be saved, so this routine is ** broken out from its caller to avoid unnecessary stack pointer movement.

74673. ** PRAGMA [schema].locking_mode ** PRAGMA [schema].locking_mode = (normal|exclusive)
74674. Length of zSql in bytes.
74675. **comment:** **** Begin Proxy Locking

Proxy locking is a "uber-locking-method" in this sense: It uses the ** other locking methods on secondary lock files. Proxy locking is a ** meta-layer over top of the primitive locking implemented above. For ** this reason, the division that implements proxy locking is deferred ** until late in the file (here) after all of the other I/O methods have ** been defined - so that the primitive locking methods are available ** as services to help with the implementation of proxy locking. ** * * * * * The default locking schemes in SQLite use byte-range locks on the ** database file to coordinate safe, concurrent access by multiple readers ** and writers [<http://sqlite.org/lockingv3.html>]. The five file locking ** states (UNLOCKED, PENDING, SHARED, RESERVED, EXCLUSIVE) are implemented ** as POSIX read & write locks over fixed set of locations (via fcntl). ** on AFP and SMB only exclusive byte-range locks are available via fcntl ** with _IOWR('z', 23, struct ByteRangeLockPB2) to track the same 5 states. ** To simulate a F_RDLCK on the shared range, on AFP a randomly selected ** address in the shared range is taken for a SHARED lock, the entire ** shared range is taken for an EXCLUSIVE lock): *** * * * * *
PENDING_BYT 0x40000000 ** RESERVED_BYT 0x40000001 ** SHARED_RANGE 0x40000002 -> 0x40000200 *** * * * * * This works well on the local file system, but shows a nearly 100x ** slowdown in read performance on AFP because the AFP client disables ** the read cache when byte-range locks are present. Enabling the read ** cache exposes a cache coherency problem that is present on all OS X ** supported network file systems. NFS and AFP both observe the ** close-to-open semantics for ensuring cache coherency ** [http://nfs.sourceforge.net/#faq_a8], which does not effectively ** address the requirements for concurrent database access by multiple ** readers and writers ** [<http://www.nabble.com/SQLite-on-NFS-cache-coherency-td15655701.html>]. *** * * * * * To address the performance and cache coherency issues, proxy file locking ** changes the way database access is controlled by limiting access to a ** single host at a time and moving file locks off of the database file ** and onto a proxy file on the local file system. *** * * * * * Using proxy locks ** ----- * * * * * C APIs * * * * *
sqlite3_file_control(db, dbname, SQLITE_FCNTL_SET_LOCKPROXYFILE, ** <proxy_path> | ":auto"); ** sqlite3_file_control(db, dbname,
SQLITE_FCNTL_GET_LOCKPROXYFILE, ** &<proxy_path>); *** * * * * * SQL pragmas *** * * * * * PRAGMA [database].lock_proxy_file=<proxy_path> | :auto: **
PRAGMA [database].lock_proxy_file ** * * * * * Specifying ":auto:" means that if there is a conch file with a matching ** host ID in it, the proxy path in the conch file will be used, otherwise ** a proxy path based on the user's temp dir ** (via fcnstr(_CS_DARWIN_USER_TEMP_DIR,...)) will be used and the ** actual proxy file name is generated from the name and path of the ** database file. For example: *** * * * * * For database path "/Users/me/foo.db" ** The lock path will be "
<tmpdir>/sqliteplocks/_Users_me_foo.db:auto:" *** * * * * * Once a lock proxy is configured for a database connection, it can not ** be removed, however it may be switched to a different proxy path via ** the above APIs (assuming the conch file is not being held by another ** connection or process). *** * * * * * How proxy locking works ** ----- * * * * * Proxy file locking relies primarily on two new supporting files: *** * * * * * conch file to limit access to the database file to a single host ** at a time ** * * * * * proxy file to act as a proxy for the advisory locks normally ** taken on the database ** * * * * * The conch file - to use a proxy file, sqlite must first "hold the conch" ** by taking an sqlite-style shared lock on the conch file, reading the ** contents and comparing the host's unique host ID (see below) and lock ** proxy path against the values stored in the conch. The conch file is ** stored in the same directory as the database file and the file name ** is patterned after the database file name as ".<dbname>-conch". ** If the conch file does not exist, or its contents do not match the ** host ID and/or proxy path, then the lock is escalated to an exclusive ** lock and the conch file contents is updated with the host ID and proxy ** path and the lock is downgraded to a shared lock again. If the conch ** is held by another process (with a shared lock), the exclusive lock ** will fail and SQLITE_BUSY is returned. *** * * * * * The proxy file - a single-byte file used for all advisory file locks ** normally taken on the database file. This allows for safe sharing ** of the database file for multiple readers and writers on the same ** host (the conch ensures that they all use the same local lock file). *** * * * * * Requesting the lock proxy does not immediately take the conch, it is ** only taken when the first request to lock database file is made. ** This matches the semantics of the traditional locking behavior, where ** opening a connection to a database file does not take a lock on it. ** The shared lock and an open file descriptor are maintained until ** the connection to the database is closed. *** * * * * * The proxy file and the lock file are never deleted so they only need ** to be created the first time they are used. *** * * * * * Configuration options ** ----- * * * * * SQLITE_PREFER_PROXY_LOCKING ** * * * * * Database files accessed on non-local file systems are ** automatically configured for proxy locking, lock files are ** named automatically using the same logic as ** PRAGMA lock_proxy_file=":auto:" *** * * * * *
SQLITE_PROXY_DEBUG ** * * * * * Enables the logging of error messages during host id file ** retrieval and creation *** * * * * * LOCKPROXYDIR ** * * * * * Overrides the default directory used for lock proxy files that ** are named automatically via the ":auto:" setting *** * * * * * SQLITE_DEFAULT_PROXYDIR_PERMISSIONS *** * * * * * Permissions to use when creating a directory for storing the ** lock proxy files, only used when LOCKPROXYDIR is not set. *** * * * * * As mentioned above, when compiled with SQLITE_PREFER_PROXY_LOCKING, ** setting the environment variable SQLITE_FORCE_PROXY_LOCKING to 1 will ** force proxy locking to be used for every database file opened, and 0 ** will force automatic proxy locking to be disabled for all database ** files (explicitly calling the SQLITE_FCNTL_SET_LOCKPROXYFILE pragma or ** sqlite_file_control API is not affected by SQLITE_FORCE_PROXY_LOCKING).

74682. '
74683. Now that the read-lock has been obtained, check that neither the ** value in the aReadMark[] array or the contents of the wal-index ** header have changed. *** * * * * * It is necessary to check that the wal-index header did not change ** between the time it was read and when the shared-lock was obtained ** on WAL_READ_LOCK(mxI) was obtained to account for the possibility ** that the log file may have been wrapped by a writer, or that frames ** that occur later in the log than pWal->hdr.mxFrame may have been ** copied into the database by a checkpoint. If either of these things ** happened, then reading the database with the current value of ** pWal->hdr.mxFrame risks reading a corrupted snapshot. So, retry ** instead. *** * * * * * Before checking that the live wal-index header has

not changed ** since it was read, set Wal.minFrame to the first frame in the wal ** file that has not yet been checkpointed. This client will not need ** to read any frames earlier than minFrame from the wal file - they ** can be safely read directly from the database file. ** ** Because a ShmBarrier() call is made between taking the copy of ** nBackfill and checking that the wal-header in shared-memory still ** matches the one cached in pWal->hdr, it is guaranteed that the ** checkpointer that set nBackfill was not working with a wal-index ** header newer than that cached in pWal->hdr. If it were, that could ** cause a problem. The checkpointer could omit to checkpoint ** a version of page X that lies before pWal->minFrame (call that version ** A) on the basis that there is a newer version (version B) of the same ** page later in the wal file. But if version B happens to like past ** frame pWal->hdr.mxFrame - then the client would incorrectly assume ** that it can read version A from the database file. However, since ** we can guarantee that the checkpointer that set nBackfill could not ** see any pages past pWal->hdr.mxFrame, this problem does not come up.

***** This file contains C code to implement the TreeView debugging routines. ** These routines print a parse tree to standard output for debugging and ** analysis. ** ** The interfaces in this file is only available when compiling ** with SQLITE_DEBUG.

74956. **comment:** ** 2008 December 3 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This module implements an object we call a "RowSet". ** ** The RowSet object is a collection of rowids. Rowids ** are inserted into the RowSet in an arbitrary order. Inserts ** can be intermixed with tests to see if a given rowid has been ** previously inserted into the RowSet. ** ** After all inserts are finished, it is possible to extract the ** elements of the RowSet in sorted order. Once this extraction ** process has started, no new elements may be inserted. ** ** Hence, the primitive operations for a RowSet are: ** ** CREATE ** INSERT ** TEST ** SMALLEST ** DESTROY ** ** The CREATE and DESTROY primitives are the constructor and destructor, ** obviously. The INSERT primitive adds a new element to the RowSet. ** TEST checks to see if an element is already in the RowSet. SMALLEST ** extracts the least value from the RowSet. ** ** The INSERT primitive might allocate additional memory. Memory is ** allocated in chunks so most INSERTs do no allocation. There is an ** upper bound on the size of allocated memory. No memory is freed ** until DESTROY. ** ** The TEST primitive includes a "batch" number. The TEST primitive ** will only see elements that were inserted before the last change ** in the batch number. In other words, if an INSERT occurs between ** two TESTs where the TESTs have the same batch number, then the ** value added by the INSERT will not be visible to the second TEST. ** The initial batch number is zero, so if the very first TEST contains ** a non-zero batch number, it will see all prior INSERTs. ** ** No INSERTs may occur after a SMALLEST. An assertion will fail if ** that is

attempted. *** The cost of an INSERT is roughly constant. (Sometimes new memory ** has to be allocated on an INSERT.) The cost of a TEST with a new ** batch number is O(NlogN) where N is the number of elements in the RowSet. ** The cost of a TEST using the same batch number is O(logN). The cost ** of the first SMALLEST is O(NlogN). Second and subsequent SMALLEST ** primitives are constant time. The cost of DESTROY is O(N). *** TEST and SMALLEST may not be used by the same RowSet. This used to ** be possible, but the feature was not used, so it was removed in order ** to simplify the code.

74984. ** Generate code that will evaluate all == and IN constraints for an ** index scan. *** For example, consider table t1(a,b,c,d,e,f) with index i1(a,b,c). ** Suppose the WHERE clause is this: a==5 AND b IN (1,2,3) AND c>5 AND c<10 ** The index has as many as three equality constraints, but in this ** example, the third "c" value is an inequality. So only two ** constraints are coded. This routine will generate code to evaluate ** a==5 and b IN (1,2,3). The current values for a and b will be stored ** in consecutive registers and the index of the first register is returned. *** In the example above nEq==2. But this subroutine works for any value ** of nEq including 0. If nEq==0, this routine is nearly a no-op. ** The only thing it does is allocate the pLevel->iMem memory cell and ** compute the affinity string. *** The nExtraReg parameter is 0 or 1. It is 0 if all WHERE clause constraints ** are == or IN and are covered by the nEq. nExtraReg is 1 if there is ** an inequality constraint (such as the "c>=5 AND c<10" in the example) that ** occurs after the nEq quality constraints. *** This routine allocates a range of nEq+nExtraReg memory cells and returns ** the index of the first memory cell in that range. The code that ** calls this routine will use that memory range to store keys for ** start and termination conditions of the loop. ** key value of the loop. If one or more IN operators appear, then ** this routine allocates an additional nEq memory cells for internal ** use. *** Before returning, *pzAff is set to point to a buffer containing a ** copy of the column affinity string of the index allocated using ** sqlite3DbMalloc(). Except, entries in the copy of the string associated ** with equality constraints that use BLOB or NONE affinity are set to ** SQLITE_AFF_BLOB. This is to deal with SQL such as the following: *** CREATE TABLE t1(a TEXT PRIMARY KEY, b); ** SELECT ... FROM t1 AS t2, t1 WHERE t1.a = t2.b; *** In the example above, the index on t1(a) has TEXT affinity. But since ** the right hand side of the equality constraint (t2.b) has BLOB/NONE affinity, ** no conversion should be attempted before using a t2.b value as part of ** a key to search the index. Hence the first byte in the returned affinity ** string in this example would be set to SQLITE_AFF_BLOB.

74985. expr ::= expr CONCAT expr

75037. ** Finalize the statement handle at pCsr->pStmt. *** Or, if that statement handle is one created by fts3CursorSeekStmt(), ** and the Fts3Table.pSeekStmt slot is currently NULL, save the statement ** pointer there instead of finalizing it.

75038. ** Convert zNum to a 64-bit signed integer. zNum must be decimal. This ** routine does *not* accept hexadecimal notation. *** If the zNum value is representable as a 64-bit two's-complement ** integer, then write that value into *pNum and return 0. *** If zNum is exactly 9223372036854775808, return 2. This special ** case is broken out because while 9223372036854775808 cannot be a ** signed 64-bit integer, its negative -9223372036854775808 can be. *** If zNum is too big for a 64-bit integer and is not ** 9223372036854775808 or if zNum contains any non-numeric text, ** then return 1. *** length is the number of bytes in the string (bytes, not characters). ** The string is not necessarily zero-terminated. The encoding is ** given by enc.

75039. 1490

75040. Low-level mutex interface

75041. expr ::= CAST LP expr AS typetoken RP

75042. Look up the table being altered.

75043. ** Allocate or return the aggregate context for a user function. A new ** context is allocated on the first call. Subsequent calls return the ** same context that was returned on prior calls.

75044. The module for this tokenizer

75045. ** Read the last entry (most recently pushed) from the hint blob *pHint ** and then remove the entry. Write the two values read to *piAbsLevel and ** *pnInput before returning. *** If no error occurs, return SQLITE_OK. If the hint blob in *pHint does ** not contain at least two valid varints, return SQLITE_CORRUPT_VTAB.

75046. Restriction 17: If the sub-query is a compound SELECT, then it must ** use only the UNION ALL operator. And none of the simple select queries ** that make up the compound SELECT are allowed to be aggregate or distinct ** queries.

75047. True for a savepoint rollback

75048. The parse context of the CREATE TRIGGER statement

75049. 2nd parameter to sqlite3_bind out of range

75050. **comment:** Opcodes that are used as the bottom of a loop (OP_Next, OP_Prev, ** OP_VNext, or OP_SorterNext) all jump here upon ** completion. Check to see if sqlite3_interrupt() has been called ** or if the progress callback needs to be invoked. *** This code uses unstructured "goto" statements and does not look clean. ** But that is not due to sloppy coding habits. The code is written this ** way for performance, to avoid having to run the interrupt and progress ** checks on every opcode. This helps sqlite3_step() to run about 1.5% ** faster according to "valgrind --tool=cachegrind".

label: code-design

75051. Shared memory associated with this inode

75052. Expr. to advance to next matching row

75053. Root page of table

75054. ** This is called to code the required FOR EACH ROW triggers for an operation ** on table pTab. The operation to code triggers for (INSERT, UPDATE or DELETE) ** is given by the op parameter. The tr_tm parameter determines whether the ** BEFORE or AFTER triggers are coded. If the operation is an UPDATE, then ** parameter pChanges is passed the list of columns being modified. *** If there are no triggers that fire at the specified time for the specified ** operation on pTab, this function is a no-op. *** The reg argument is the address of the first in an array of registers ** that contain the values substituted for the new.* and old.* references ** in the trigger program. If N is the number of columns in table pTab ** (a copy of pTab->nCol), then registers are populated as follows: *** Register Contains ** ----- ** reg+0 OLD.rowid ** reg+1 OLD.* value of left-most column of pTab ** ** reg+N OLD.* value of right-most column of pTab ** reg+N+1 NEW.rowid ** reg+N+2 OLD.* value of left-most column of pTab ** ** reg+N+N+1 NEW.* value of right-most column of pTab ** ** For ON DELETE triggers, the registers containing the NEW.* values will ** never be accessed by the trigger program, so they are not allocated or ** populated by the caller (there is no data to populate them with anyway). ** Similarly, for ON INSERT triggers the values stored in the OLD.* registers ** are never accessed, and so are not allocated by the caller. So, for an ** ON INSERT trigger, the value passed to this function as

parameter reg ** is not a readable register, although registers (reg+N) through ** (reg+N+N+1) are. *** Parameter orconf is the default conflict resolution algorithm for the ** trigger program to use (REPLACE, IGNORE etc.). Parameter ignoreJump ** is the instruction that control should jump to if a trigger program ** raises an IGNORE exception.

75055. **comment:** ** The SQLITE_AFF_MASK values masks off the significant bits of an ** affinity value.

75056. INSERT_CONTENT

75057. ***** sqlite3_value_***** The following routines extract information from a Mem or sqlite3_value ** structure.

75058. ** This is a magic string that appears at the beginning of every ** SQLite database in order to identify the file as a real database. *** You can change this value at compile-time by specifying a ** -DSQLITE_FILE_HEADER="..." on the compiler command-line. The ** header must be exactly 16 bytes including the zero-terminator so ** the string itself should be 15 characters long. If you change ** the header, then your custom library will not be able to read ** databases generated by the standard tools and the standard tools ** will not be able to read databases created by your custom library.

75059. one of TK_DELETE, TK_INSERT, TK_UPDATE

75060. Built-in coalesce() or ifnull()

75061. Amount of payload held locally, not on overflow

75062. ** Deallocate and destroy a parser. Destructors are called for ** all stack elements before shutting the parser down. *** If the fts5YYPARSEFREE NEVERNULL macro exists (for example because it ** is defined in a %include section of the input grammar) then it is ** assumed that the input pointer is never NULL.

75063. List of names of LHS of the assignment

75064. ** CAPI3REF: Authorizer Action Codes *** The [sqlite3_set_authorizer()] interface registers a callback function ** that is invoked to authorize certain SQL statement actions. The ** second parameter to the callback is an integer code that specifies ** what action is being authorized. These are the integer action codes that ** the authorizer callback may be passed. *** These action code values signify what kind of operation is to be ** authorized. The 3rd and 4th parameters to the authorization ** callback function will be parameters or NULL depending on which of these ** codes is used as the second parameter. ^The 5th parameter to the ** authorizer callback is the name of the database ("main", "temp", ** etc.) if applicable.^ ^The 6th parameter to the authorizer callback ** is the name of the inner-most trigger or view that is responsible for ** the access attempt or NULL if this access attempt is directly from ** top-level SQL code.

75065. Fall through for the RTREE_EQ case

75066. End if(affinity_ok)

75067. ** Equivalent to: *** char *fts5EntryKey(Fts5HashEntry *pEntry){ return zKey; }

75068. Check the table schemas match

75069. New object to return

75070. ** Implementation of the instr() function. *** instr(haystack,needle) finds the first occurrence of needle ** in haystack and returns the number of previous characters plus 1, ** or 0 if needle does not occur within haystack. *** If both haystack and needle are BLOBS, then the result is one more than ** the number of bytes in haystack prior to the first occurrence of needle, ** or 0 if needle never occurs in haystack.

75071. The database file

75072. Verify that the database still has the same name as it did when ** it was originally opened.

75073. 7: (start_constraints && startEq && bRev)

75074. Iterator object

75075. ** Return a pointer to the name of a variable in the given VList that ** has the value iVal. Or return a NULL if there is no such variable in ** the list

75076. Available backtrace slots

75077. **comment:** ** Exactly one of the following macros must be defined in order to ** specify which memory allocation subsystem to use. ***
SQLITE_SYSTEM_MALLOC // Use normal system malloc() ** SQLITE_WIN32_MALLOC // Use Win32 native heap API ** SQLITE_ZERO_MALLOC // Use a stub allocator that always fails ** SQLITE_MEMDEBUG // Debugging version of system malloc() *** On Windows, if the SQLITE_WIN32_MALLOC_VALIDATE macro is defined and the ** assert() macro is enabled, each call into the Win32 native heap subsystem ** will cause HeapValidate to be called. If heap validation should fail, an ** assertion will be triggered. *** If none of the above are defined, then set SQLITE_SYSTEM_MALLOC as ** the default.

75078. Index in p->aIndex[]

75079. Pointer to blob containing changeset

75080. Index in sqlite3.aDb[] of database holding pTab

75081. The shared memory being locked

75082. Input data

75083. Fill in the header.

75084. Create the SELECT statement to read keys from data_xxx

75085. ** CAPI3REF: Generate A Changeset From A Session Object *** Obtain a changeset containing changes to the tables attached to the ** session object passed as the first argument. If successful, ** set *ppChangeset to point to a buffer containing the changeset ** and *pnChangeset to the size of the changeset in bytes before returning ** SQLITE_OK. If an error occurs, set both *ppChangeset and *pnChangeset to ** zero and return an SQLite error code. *** A changeset consists of zero or more INSERT, UPDATE and/or DELETE changes, ** each representing a change to a single row of an attached table. An INSERT ** change contains the values of each field of a new database row. A DELETE ** contains the original values of each field of a deleted database row. An ** UPDATE change contains the original values of each field of an updated ** database row along with the updated values for each updated non-primary-key ** column. It is not possible for an UPDATE change to represent a change that ** modifies the values of primary key columns. If such a change is made, it ** is represented in a changeset as a DELETE followed by an INSERT. *** Changes are not recorded for rows that have NULL values stored in one or ** more of their PRIMARY KEY columns. If such a row is inserted or deleted, ** no corresponding change is present in the changesets returned by this ** function. If an existing row with one or more NULL values stored in ** PRIMARY KEY columns is updated so that all PRIMARY KEY columns are non-NUL, ** only an INSERT is appears in the changeset. Similarly, if an existing row ** with non-NUL PRIMARY KEY values is updated so that one or more of its ** PRIMARY KEY columns are set to NULL, the resulting changeset contains a ** DELETE change only. *** The contents of a changeset may be traversed using an iterator created ** using the [sqlite3changeset_start()] API. A changeset may be applied to ** a database with a compatible schema using the [sqlite3changeset_apply()] ** API. *** Within a changeset generated by this function, all changes related to a ** single table are grouped together. In other words, when iterating through ** a changeset or when applying a changeset to a database, all changes related ** to a single table are processed before moving on to the next table. Tables ** are sorted in the same order in which they were attached (or auto-attached) ** to the sqlite3_session object. The order in which the changes related to ** a single table are stored is undefined.
