*** Following a successful call to this function, it is the responsibility of ** the caller to eventually free the buffer that *ppChangeset points to using ** [sqlite3_free()]. *** <h3>Changeset Generation</h3> *** Once a table has been attached to a session object, the session object ** records the primary key values of all new rows inserted into the table. ** It also records the original primary key and other column values of any ** deleted or updated rows. For each unique primary key value, data is only ** recorded once - the first time a row with said primary key is inserted, ** updated or deleted in the lifetime of the session. **** There is one exception to the previous paragraph: when a row is inserted, ** updated or deleted, if one or more of its primary key columns contain a ** NULL value, no record of the change is made. *** The session object therefore accumulates two types of records - those ** that consist of primary key values only (created when the user inserts ** a new record) and those that consist of the primary key values and the ** original values of other table columns (created when the users deletes ** or updates a record). *** When this function is called, the requested changeset is created using ** both the accumulated records and the current contents of the database ** file. Specifically: *** ** For each record generated by an insert, the database is queried ** for a row with a matching primary key. If one is found, an INSERT ** change is added to the changeset. If no such row is found, no change ** is added to the changeset. ** For each record generated by an update or delete, the database is ** queried for a row with a matching primary key. If such a row is ** found and one or more of the non-primary key fields have been ** modified from their original values, an UPDATE change is added to ** the changeset. Or, if no such row is found in the table, a DELETE ** change is added to the changeset. If there is a row with a matching ** primary key in the database, but all fields contain their original ** values, no change is added to the changeset. ** ** This means, amongst other things, that if a row is inserted and then later ** deleted while a session object is active, neither the insert nor the delete ** will be present in the changeset. Or if a row is deleted and then later a ** row with the same primary key values inserted while a session object is ** active, the resulting changeset will contain an UPDATE change instead of ** a DELETE and an INSERT. *** When a session object is disabled (see the [sqlite3session_enable()] API), ** it does not accumulate records when rows are inserted, updated or deleted. ** This may appear to have some counter-intuitive effects if a single row ** is written to more than once during a session. For example, if a row ** is inserted while a session object is enabled, then later deleted while ** the same session object is disabled, no INSERT record will appear in the ** changeset, even though the delete took

place while the session was disabled. ** Or, if one field of a row is updated while a session is disabled, and ** another field of the same row is updated while the session is enabled, the ** resulting changeset will contain an UPDATE change that updates both fields.

75086. Page being freed. May be NULL.

75087. The 6th parameter to db->xAuth callbacks

75088. VACUUM

75089. A sorting index used to test for distinctness

75090. Local copy of initial highlight-mask

75091. yymsp[-1].minor.yy0-overwrite-yymsp[0].minor.yy0

75092. ** Obtain a reference to an r-tree node.

75093. Reinstall the LIKE and GLOB functions. The variant of LIKE ** used will be case sensitive or not depending on the RHS.

75094. SQLITE_AFF_NUMERIC

75095. **comment:** Set the magic to VDBE_MAGIC_RUN sooner rather than later.

label: code-design

75096. Figure out the best index to use to search a pragma virtual table. ** ** There are not really any index choices. But we want to encourage the ** query planner to give == constraints on as many hidden parameters as ** possible, and especially on the first hidden parameter. So return a ** high cost if hidden parameters are unconstrained.

75097. If the page being moved is dirty and has not been saved by the latest ** savepoint, then save the current contents of the page into the ** sub-journal now. This is required to handle the following scenario: ** ** BEGIN; ** <journal page X, then modify it in memory> ** SAVEPOINT one; ** <Move page X to location Y> ** ROLLBACK TO one; ** ** If page X were not written to the sub-journal here, it would not ** be possible to restore its contents when the "ROLLBACK TO one" ** statement were processed. ** ** subjournalPage() may need to allocate space to store pPg->pjno into ** one or more savepoint bitvecs. This is the reason this function ** may return SQLITE_NOMEM.

75098. Number of unixShm objects pointing to this

75099. ** Make sure the TEMP database is open and available for use. Return ** the number of errors. Leave any error messages in the pParse structure.

75100. Records are always returned in ascending order of (name, path). ** If this will satisfy the client, set the orderByConsumed flag so that ** SQLite does not do an external sort.

75101. Last insert rowid (sqlite3.lastRowid)

75102. ** Return the full pathname of the underlying database file. Return ** an empty string if the database is in-memory or a TEMP database. ** ** The pager filename is invariant as long as the pager is ** open so it is safe to access without the BtShared mutex.

75103. Map from parent key columns to child table columns

75104. key_opt ::= KEY expr

75105. The record flows over onto one or more overflow pages. In ** this case the whole cell needs to be parsed, a buffer allocated ** and accessPayload() used to retrieve the record into the ** buffer before VdbeRecordCompare() can be called. ** ** If the record is corrupt, the xRecordCompare routine may read ** up to two varints past the end of the buffer. An extra 18 ** bytes of padding is allocated at the end of the buffer in ** case this happens.

75106. 1270

75107. ** The page that pCur currently points to has just been modified in ** some way. This function figures out if this modification means the ** tree needs to be balanced, and if so calls the appropriate balancing ** routine. Balancing routines are: ** ** balance_quick() ** balance_deeper() ** balance_nonroot()

75108. Loop through the returned columns. Set nStr to the number of bytes of ** space required to store a copy of each column name, including the ** nul-terminator byte.

75109. True for first term on page

75110. ** 2008 June 13 ** ** The author disclaims copyright to this source code. 75246. Name of the file (UTF-8)

75247. p->flags holds EP_Collate and p->pLeft->flags does not. And ** p->x.pSelect cannot. So if p->x.pLeft exists, it must hold at ** least one EP_Collate. Thus the following two ALWAYS.

75248. **comment:** ** In addition to its current configuration, have the Fts3MultiSegReader ** passed as the 4th argument also scan the doclist for term zTerm/nTerm. ** ** SQLITE_OK is returned if no error occurs, otherwise an SQLite error code.

label: code-design

75249. ** This function starts a write transaction on the WAL. *** A read transaction must have already been started by a prior call ** to sqlite3WalBeginReadTransaction(). *** If another thread or process has written into the database since ** the read transaction was started, then it is not possible for this ** thread to write as doing so would cause a fork. So this routine ** returns SQLITE_BUSY in that case and no write transaction is started. *** There can only be a single writer active at a time.

75250. Append to this SrcList. NULL creates a new SrcList

75251. Which tables are currently available

75252. ** CAPI3REF: Online Backup Object *** The sqlite3_backup object records state information about an ongoing ** online backup operation. ^The sqlite3_backup object is created by ** a call to [sqlite3_backup_init()] and is destroyed by a call to ** [sqlite3_backup_finish()]. *** See Also: [Using the SQLite Online Backup API]

75253. ** Code an OP_TableLock instruction for each table locked by the ** statement (configured by calls to sqlite3TableLock()).

75254. The associated database

75255. ** Search the free-list on page pPg for space to store a cell nByte bytes in ** size. If one can be found, return a pointer to the space and remove it ** from the free-list. *** If no suitable space can be found on the free-list, return NULL. ** ** This function may detect corruption within pPg. If corruption is ** detected then *pRc is set to SQLITE_CORRUPT and NULL is returned. ** ** Slots on the free list that are between 1 and 3 bytes larger than nByte ** will be ignored if adding the extra space to the fragmentation count ** causes the fragmentation count to exceed 60.

75256. ** Advance iterator pIter to the next entry. ** ** This version of fts5SegIterNext() is only used by reverse iterators.

75257. Make the JSON in p the result of the SQL function.

75258. ** Move the iterator passed as the only argument to the previous entry.

75259. Update the sqlite_sequence table by storing the content of the ** maximum rowid counter values recorded while inserting into ** autoincrement tables.

75260. porter rule condition: (m > 1 and (*S or *T))

75261. Append the table key to the end of the index. For WITHOUT ROWID ** tables (when pPk!=0) this will be the declared PRIMARY KEY. For ** normal tables (when pPk==0) this will be the rowid.

75262. ** In the amalgamation, the parse.c file generated by lemon and the ** tokenize.c file are concatenated. In that case, sqlite3RunParser() ** has access to the the size of the yyParser object and so the parser ** engine can be allocated from stack. In that case, only the ** sqlite3ParserInit() and sqlite3ParserFinalize() routines are invoked ** and the sqlite3ParserAlloc() and sqlite3ParserFree() routines can be ** omitted.

75263. pExpr is original. Make a new entry in pAggInfo->aFunc[]

75264. **comment:** A malloc must have failed

label: code-design

75265. **comment:** This routine is never used in single-threaded mode

label: requirement

75266. OP_Found will use an unpacked key

75267. Bytes buffered before opening the file

75268. ** Return a pointer to a subexpression of pVector that is the i-th ** column of the vector (numbered starting with 0). The caller must ** ensure that i is within range. *** If pVector is really a scalar (and "scalar" here includes subqueries ** that return a single column!) then return pVector unmodified. ** ** pVector retains ownership of the returned subexpression. ** ** If the vector is a (SELECT ...) then the expression returned is ** just the expression for the i-th term of the result set, and may ** not be ready for evaluation because the table cursor has not yet ** been positioned.

75269. Payload to be inserted

75270. Return segments in order from oldest to newest.

75271. ***** Continuing where we left off in pragma.c *****

75272. ***** Begin file dbstat.c *****

75273. The FTS3 table

75274. Page number array for hash table

75275. OUT: Final checksum value output

75276. ***** End of legacy.c *****

75277. ** Add a new module argument to pTable->azModuleArg[]. ** The string is not copied - the pointer is stored. The ** string will be freed automatically when the table is ** deleted.

75278. First register in OLD.* array

75279. Create a record for this index entry as it should appear after ** the insert or update. Store that record in the aRegIdx[ix] register

75280. ***** End %syntax_error code *****

75281. OUT: Number of backfilled frames in WAL

75282. Left side of comparison

75283. Assuming the wal-index file was successfully mapped, populate the ** page number array and hash table entry.

75284. Tokenizer for this table

75285. Total bytes of data (incl. structure)

75286. First in linked list of saved aux-data

75287. Check that the pointer pOld points to a valid, non-free block.

75288. Next sample to test

75289. Register that is true if RHS contains NULL values

75290. If the first attempt to open the database file fails and the bRetry ** flag is set, this means that the db was not opened because it seemed ** to be a wal-mode db. But, this may have happened due to an earlier ** RBU vacuum operation leaving an old wal file in the directory. ** If this is the case, it will have been checkpointed and deleted ** when the handle was closed and a second attempt to open the ** database may succeed.

75291. 1. first try to open/create the file ** 2. if that fails, and this is a lock file (not-conch), try creating ** the parent directories and then try again. ** 3. if that fails, try to open the file read-only ** otherwise return BUSY (if lock file) or CANTOPEN for the conch file

75292. The next block of code is equivalent to: ** ** pIter += getVarint(pIter, (u64*)&pInfo->nKey); ** ** The code is inlined to avoid a function call.

75293. ** The following 256 byte lookup table is used to support SQLites built-in ** equivalents to the following standard library functions: ** ** isspace() 0x01 ** isalpha() 0x02 ** isdigit() 0x04 ** isalnum() 0x06 ** isxdigit() 0x08 ** toupper() 0x20 ** SQLite identifier character 0x40 ** Quote character 0x80 ** ** Bit 0x20 is set if the mapped character requires translation to upper ** case. i.e. if the character is a lower-case ASCII character. ** If x is a lower-case ASCII character, then its upper-case equivalent ** is (x - 0x20). Therefore toupper() can be implemented as: ** ** (x & ~map[x]&0x20) ** ** The equivalent of

tolower() is implemented using the sqlite3UpperToLower[] ** array. tolower() is used more often than toupper() by SQLite. *** Bit 0x40 is set if the character is non-alphanumeric and can be used in an ** SQLite identifier. Identifiers are alphanumeric, "_", "\$", and any ** non-ASCII UTF character. Hence the test for whether or not a character is ** part of an identifier is 0x46.

75294. VM to add scanstatus() to

75295. ** This function is used to create the text of expressions of the form: ** name=<constant1> OR name=<constant2> OR ... ** ** If argument zWhere is NULL, then a pointer string containing the text ** "name=<constant>" is returned, where <constant> is the quoted version ** of the string passed as argument zConstant. The returned buffer is ** allocated using sqlite3DbMalloc(). It is the responsibility of the ** caller to ensure that it is eventually freed. *** If argument zWhere is not NULL, then the string returned is ** "<where> OR name=<constant>", where <where> is the contents of zWhere. ** In this case zWhere is passed to sqlite3DbFree() before returning. **

75296. Mask of FTS5_TOKENIZE_* flags

75297. ** Append SegReader object pNew to the end of the pCsr->apSegment[] array.

75298. Page number

75299. True if WAL file exists

75300. 2,3

75301. Assert that operands are never NULL

75302. columnname ::= nm typetoken

75303. The SrcList to be enlarged

75304. **comment:** ** Return TRUE if the WHERE clause term pTerm is of a form where it ** could be used with an index to access pSrc, assuming an appropriate ** index existed.

label: code-design

75305. Update the in-memory representation of all UNIQUE indices by converting ** the final rowid column into one or more columns of the PRIMARY KEY.

75306. EOF when i equals or exceeds this value

75307. ** Advance iterator pIter to the next entry. *** If an error occurs, Fts5Index.rc is set to an appropriate error code. It ** is not considered an error if the iterator reaches EOF. If an error has ** already occurred when this function is called, it is a no-op.

75308. Deallocate page if true

75309. ** For some Windows sub-platforms, the _beginthreadex() / _endthreadex() ** functions are not available (e.g. those not using MSVC, Cygwin, etc).

75310. Opcode: Found P1 P2 P3 P4 ** Synopsis: key=r[P3@P4] *** If P4==0 then register P3 holds a blob constructed by MakeRecord. If ** P4>0 then register P3 is the first of P4 registers that form an unpacked ** record. *** Cursor P1 is on an index btree. If the record identified by P3 and P4 ** is a prefix of any entry in P1 then a jump is made to P2 and ** P1 is left pointing at the matching entry. *** This operation leaves the cursor in a state where it can be ** advanced in the forward direction. The Next instruction will work, ** but not the Prev instruction. *** See also: NotFound, NoConflict, NotExists. SeekGe

75311. A connection with the read-uncommitted flag set will never try to ** obtain a read-lock using this function. The only read-lock obtained ** by a connection in read-uncommitted mode is on the sqlite_master ** table, and that lock is obtained in BtreeBeginTrans().

75312. If pWalker->eCode is 2 then any term of the expression that comes from ** the ON or USING clauses of a left join disqualifies the expression ** from being considered constant.

75313. ** End of highlight() implementation. *****

75314. Zero-length table names are allowed

75315. IMP: R-51971-34154

75316. Total leaves written to level 0

75317. Create new databases in format 1

75318. ** Page type flags. An ORed combination of these flags appear as the ** first byte of on-disk image of every BTree page.

75319. The WHERE processing context

75320. OUT: Allocated Wal handle

75321. RHS of LIKE/GLOB ends with wildcard

75322. Now update the actual sibling pages. The order in which they are updated ** is important, as this code needs to avoid disrupting any page from which ** cells may still to be read. In practice, this means: ** ** (1) If cells are moving left (from apNew[iPg] to apNew[iPg-1]) ** then it is not safe to update page apNew[iPg] until after ** the left-hand sibling apNew[iPg-1] has been updated. ** ** (2) If cells are moving right (from apNew[iPg] to apNew[iPg+1]) ** then it is not safe to update page apNew[iPg] until after ** the right-hand sibling apNew[iPg+1] has been updated. ** ** If neither of the above apply, the page is safe to update. *** The iPg value in the following loop starts at nNew-1 goes down ** to 0, then back up to nNew-1 again, thus making two passes over ** the pages. On the initial downward pass, only condition (1) above ** needs to be tested because (2) will always be true from the previous ** step. On the upward pass, both conditions are always true, so the ** upwards pass simply processes pages that were missed on the downward ** pass.

75323. If it did not delete it, the row-trigger may still have modified ** some of the columns of the row being updated. Load the values for ** all columns not modified by the update statement into their ** registers in case this has happened.

75324. frame == (aHash[x]+iZero)

75325. Number of tokens in phrase

75326. OUT: Parsed query structure

75327. Indicates an exclusive lock has been obtained

75328. ** If the second argument is not NULL, release any allocations associated ** with the memory cells in the p->aMem[] array. Also free the UnpackedRecord ** structure itself, using sqlite3DbFree(). *** This function is used to free UnpackedRecord structures allocated by ** the vdbeUnpackRecord() function found in vdbeapi.c.

75329. The WherePath to check

75330. Gather entropy into this buffer

75331. Record the number of outstanding lookaside allocations in schema Tables ** prior to doing any free() operations. Since schema Tables do not use ** lookaside, this number should not change.

75332. Table being modified

75333. Column to scan for

75334. all memory is allocated, proxys are created and assigned, ** switch the locking context and pMethod then return.

75335. Maximum number of cells for pNode

75336. If currently processing the PRIMARY KEY of a WITHOUT ROWID ** table, only conflict if the new PRIMARY KEY values are actually ** different from the old. *** For a UNIQUE index, only conflict if the PRIMARY KEY values ** of the matched index row are different from the original PRIMARY ** KEY values of this row before the update.

75337. **comment:** ** CAPI3REF: OS Interface Object ** ** An instance of the sqlite3_vfs object defines the interface between ** the SQLite core and the underlying operating system. The "vfs" ** in the name of the object stands for "virtual file system". See ** the [VFS | VFS documentation] for further information. *** ** The value of the iVersion field is initially 1 but may be larger in ** future versions of SQLite. Additional fields may be appended to this ** object when the iVersion value is increased. Note that the structure ** of the sqlite3_vfs object changes in the transaction between ** SQLite version 3.5.9 and 3.6.0 and yet the iVersion field was not ** modified. *** The szOsFile field is the size of the subclassed [sqlite3_file] ** structure used by this VFS. mxPathname is the maximum length of ** a pathname in this VFS. *** Registered sqlite3_vfs objects are kept on a linked list formed by ** the pNext pointer. The [sqlite3_vfs_register()] ** and [sqlite3_vfs_unregister()] interfaces manage this list ** in a thread-safe way. The [sqlite3_vfs_find()] interface ** searches the list. Neither the application code nor the VFS ** implementation should use the pNext pointer. *** The pNext field is the only field in the sqlite3_vfs ** structure that SQLite will ever modify. SQLite will only access ** or modify this field while holding a particular static mutex. ** The application should never modify anything within the sqlite3_vfs ** object once the object has been registered. *** The zName field holds the name of the VFS module. The name must ** be unique across all VFS modules. *** [[sqlite3_vfs.xOpen]] ** ^SQLite guarantees that the zFilename parameter to xOpen ** is either a NULL pointer or string obtained ** from xFullPathname() with an optional suffix added. ** ^If a suffix is added to the zFilename parameter, it will ** consist of a single "-" character followed by no more than ** 11 alphanumeric and/or "-" characters. ** ^SQLite further guarantees that ** the string will be valid and unchanged until xClose() is ** called. Because of the previous sentence, ** the [sqlite3_file] can safely store a pointer to the ** filename if it needs to remember the filename for some reason. ** If the zFilename parameter to xOpen is a NULL pointer then xOpen ** must invent its own temporary name for the file. ^Whenever the ** xFilename parameter is NULL it will also be the case that the ** flags parameter will include [SQLITE_OPEN_DELETEONCLOSE]. *** The flags argument to xOpen() includes all bits set in ** the flags argument to [sqlite3_open_v2()]. Or if [sqlite3_open()] ** or [sqlite3_open16()] is used, then flags includes at least ** [SQLITE_OPEN_READWRITE] | [SQLITE_OPEN_CREATE]. ** If xOpen() opens a file read-only then it sets *pOutFlags to ** include [SQLITE_OPEN_READONLY]. Other bits in *pOutFlags

may be set. *** ^^(SQLite will also add one of the following flags to the xOpen() ** call, depending on the object being opened: *** ** [SQLITE_OPEN_MAIN_DB] ** [SQLITE_OPEN_MAIN_JOURNAL] ** [SQLITE_OPEN_TEMP_DB] ** [SQLITE_OPEN_TEMP_JOURNAL] ** [SQLITE_OPEN_TRANSIENT_DB] ** [SQLITE_OPEN_SUBJOURNAL] ** [SQLITE_OPEN_MASTER_JOURNAL] ** [SQLITE_OPEN_WAL] **)*** The file I/O implementation can use the object type flags to ** change the way it deals with files. For example, an application ** that does not care about crash recovery or rollback might make ** the open of a journal file a no-op. Writes to this journal would ** also be no-ops, and any attempt to read the journal would return ** SQLITE_IOERR. Or the implementation might recognize that a database ** file will be doing page-aligned sector reads and writes in a random ** order and set up its I/O subsystem accordingly. *** SQLite might also add one of the following flags to the xOpen method: *** ** [SQLITE_OPEN_DELETEONCLOSE] ** [SQLITE_OPEN_EXCLUSIVE] ** *** The [SQLITE_OPEN_DELETEONCLOSE] flag means the file should be ** deleted when it is closed. ^The [SQLITE_OPEN_DELETEONCLOSE] ** will be set for TEMP databases and their journals, transient ** databases, and subjournals. *** ^The [SQLITE_OPEN_EXCLUSIVE] flag is always used in conjunction ** with the [SQLITE_OPEN_CREATE] flag, which are both directly ** analogous to the O_EXCL and O_CREAT flags of the POSIX open() ** API. The SQLITE_OPEN_EXCLUSIVE flag, when paired with the ** SQLITE_OPEN_CREATE, is used to indicate that file should always ** be created, and that it is an error if it already exists. *** It is <i>not</i> used to indicate the file should be opened ** for exclusive access. *** ^At least szOsFile bytes of memory are allocated by SQLite ** to hold the [sqlite3_file] structure passed as the third ** argument to xOpen. The xOpen method does not have to ** allocate the structure; it should just fill it in. Note that ** the xOpen method must set the sqlite3_file.pMethods to either ** a valid [sqlite3_io_methods] object or to NULL. xOpen must do ** this even if the open fails. SQLite expects that the sqlite3_file.pMethods ** element will be valid after xOpen returns regardless of the success ** or failure of the xOpen call. *** [[sqlite3_vfs.xAccess]] ** ^The flags argument to xAccess() may be [SQLITE_ACCESS_EXISTS] ** to test for the existence of a file, or [SQLITE_ACCESS_READWRITE] to ** test whether a file is readable and writable, or [SQLITE_ACCESS_READ] ** to test whether a file is at least readable. The file can be a ** directory. *** ^SQLite will always allocate at least mxPathname+1 bytes for the ** output buffer xFullPathname. The exact size of the output buffer ** is also passed as a parameter to both methods. If the output buffer ** is not large enough, [SQLITE_CANTOPEN] should be returned. Since this is ** handled as a fatal error by SQLite, vfs implementations should endeavor ** to prevent this by setting mxPathname to a sufficiently large value. *** ^The xRandomness(), xSleep(), xCurrentTime(), and xCurrentTimeInt64() ** interfaces are not strictly a part of the filesystem, but they are ** included in the VFS structure for completeness. ** The xRandomness() function attempts to return nBytes bytes ** of good-quality randomness into zOut. The return value is ** the actual number of bytes of randomness obtained. ** The xSleep() method causes the calling thread to sleep for at ** least the number of microseconds given. ^The xCurrentTime() ** method returns a Julian Day Number for the current date and time as ** a floating point value. *** ^The xCurrentTimeInt64() method returns, as an integer, the Julian ** Day Number multiplied by 86400000 (the number of milliseconds in ** a 24-hour day). *** ^SQLite will use the xCurrentTimeInt64() method to get the current ** date and time if that method is available (if iVersion is 2 or ** greater and the function pointer is not NULL) and will fall back ** to xCurrentTime() if xCurrentTimeInt64() is unavailable. *** ^The xSetSystemCall(), xGetSystemCall(), and xNestSystemCall() interfaces ** are not used by the SQLite core. These optional interfaces are provided ** by some VFSes to facilitate testing of the VFS code. By overriding ** system calls with functions under its control, a test program can ** simulate faults and error conditions that would otherwise be difficult ** or impossible to induce. The set of system calls that can be overridden ** varies from one VFS to another, and from one version of the same VFS to the ** next. Applications that use these interfaces must be prepared for any ** or all of these interfaces to be NULL or for their behavior to change ** from one release to the next. Applications must not attempt to access ** any of these methods if the iVersion of the VFS is less than 3.

75391. ** 2001 September 15 *** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This file contains C code routines that are called by the parser ** to handle INSERT statements in SQLite.

75392. Rowid for current entry
75393. Check if the temp table already contains this key. If so, ** the row has already been included in the result set and ** can be ignored (by jumping past the Gosub below). Otherwise, ** insert the key into the temp table and proceed with processing ** the row. ** ** Use some of the same optimizations as OP_RowSetTest: If iSet ** is zero, assume that the key cannot already be present in ** the temp table. And if iSet is -1, assume that there is no ** need to insert the key into the temp table, as it will never ** be tested for.

75394. New virtual expression
75395. Opcode: ReopenIdx P1 P2 P3 P4 P5 ** Synopsis: root=P2 iDb=P3 ** ** The ReopenIdx opcode works exactly like ReadOpen except that it first ** checks to see if the cursor on P1 is already open with a root page ** number of P2 and if it is this opcode becomes a no-op. In other words, ** if the cursor is already open, do not reopen it. ** ** The ReopenIdx opcode may only be used with P5==0 and with P4 being ** a P4_KEYINFO object. Furthermore, the P3 value must be the same as ** every other ReopenIdx or OpenRead for the same cursor number. ** ** See the OpenRead opcode documentation for additional information.

75396. ELSE
75397. The sqlite_statN table does not exist. Create it. Note that a ** side-effect of the CREATE TABLE statement is to leave the rootpage ** of the new table in register pParse->regRoot. This is important ** because the OpenWrite opcode below will be needing it.

75398. OUT: New iterator
75399. Size of shared-memory regions
75400. True to set the USESEEKRESULT flag on OP_[Idx]Insert
75401. Commit by zeroing journal header
75402. At this point, any non-zero iOrderByCol values indicate that the ** ORDER BY column expression is identical to the iOrderByCol'th ** expression returned by SELECT statement pSub. Since these values ** do not necessarily correspond to columns in SELECT statement pParent, ** zero them before transferring the ORDER BY clause. ** ** Not doing this may cause an error if a subsequent call to this ** function attempts to flatten a compound sub-query into pParent ** (the only way this can happen is if the compound sub-query is ** currently part of pSub->pSrc). See ticket [d11a6e908f].

75403. Load b.apCell[] with pointers to all cells in pOld. If pOld ** contains overflow cells, include them in the b.apCell[] array ** in the correct spot. ** ** Note that when there are multiple overflow cells, it is always the ** case that they are sequential and adjacent. This invariant arises ** because multiple overflows can only occur when inserting divider ** cells into a parent on a prior balance, and divider cells are always ** adjacent and are inserted in order. There is an assert() tagged ** with "NOTE 1" in the overflow cell insertion loop to prove this ** invariant. ** ** This must be done in advance. Once the balance starts, the cell ** offset section of the btree page will be overwritten and we will no ** long be able to find the cells if a pointer to each cell is not saved ** first.

75404. ** Add an entry to the Fts5SFinder.aFirst[] array. Grow the array if ** necessary. Return SQLITE_OK if successful, or SQLITE_NOMEM if an ** error occurs.
75405. 08..0f

75406. Statement number (or 0 if has not opened stmt)
75407. Load the contents of the %_config table
75408. If one value is NULL, it is less than the other. If both values ** are NULL, return 0.
75409. moved CSE2 up
75410. Function to call when busy
75411. First character of input text
75412. Move to the next entry that matches the configured constraints.
75413. Code an OP_Expire. For an ATTACH statement, set P1 to true (expire this ** statement only). For DETACH, set it to false (expire all existing ** statements).
75414. buffer in which to construct conch name
75415. Index of column in second table
75416. A fake index object for the primary key
75417. Column to match on.
75418. Offset to next unparsed byte of the header
75419. ** The MSVC CRT on Windows CE may not have a localtime() function. ** So define a substitute.
75420. SQLITE OMIT_SCHEMA_VERSION_PRAGMAS
75421. Return no rowids earlier than this
75422. pkChng!=0 does not mean that the rowid has changed, only that ** it might have changed. Skip the conflict logic below if the rowid ** is unchanged.
75423. Write the header for the new UPDATE change. Same as the original.
75424. SQLITE_PREPARE_* flags
75425. **comment:** If the default value for the new column was specified with a ** literal NULL, then set pDflt to 0. This simplifies checking ** for an SQL NULL default below.
label: code-design
75426. ** This interface is used by the fts5vocab module.

75427. For UNIQUE indexes, verify that only one entry exists with the ** current key. The entry is unique if (1) any column is NULL ** or (2) the next entry has a different key

75428. First allowable cell index

75429. The SnippetIter object has just been initialized. The first snippet ** candidate always starts at offset 0 (even if this candidate has a ** score of 0.0).

75430. Declare the table schema to SQLite.

75431. Index name

75432. FTS cursor handle

75433. ** Truncate an open file to a specified size

75434. Make sure cursor numbers have been assigned to all entries in ** the FROM clause of the SELECT statement.

75435. If there was a master journal and this routine will return success, ** see if it is possible to delete the master journal.

75436. constructor for a JsonEachCursor object for json_each().

75437. A complex statement machine used to detect the end of a CREATE TRIGGER ** statement. This is the normal case.

75438. If a transaction is open, roll it back. This also ensures that if ** any database schemas have been modified by an uncommitted transaction ** they are reset. And that the required b-tree mutex is held to make ** the pager rollback and schema reset an atomic operation.

75439. (301) resolvetype ::= raisetype (OPTIMIZED OUT)

75440. True to use in-memory sub-journals

75441. Parent key index for this FK

75442. Use the foreground thread for this operation

75443. True if this is a VIRTUAL table

75444. VDBE cursor for the canonical data source

75445. Disables and re-enables match

75446. ** Remove entries from the sqlite_statN tables (for N in (1,2,3)) ** after a DROP INDEX or DROP TABLE command.

75447. This block codes the top of loop only. The complete loop is the ** following pseudocode (template 3): *** C: yield X, at EOF goto D ** insert the select result into <table> from R..R+n ** goto C ** D: ...

***** OVERVIEW *** The RBU extension requires that the RBU update be packaged as an ** SQLite database. The tables it expects to find are described in ** sqlite3rbu.h. Essentially, for each table xyz in the target database ** that the user wishes to write to, a corresponding data_xyz table is ** created in the RBU database and populated with one row for each row to ** update, insert or delete from the target table. *** The update proceeds in three stages: *** 1) The database is updated. The modified database pages are written ** to a *-oal file. A *-oal file is just like a *-wal file, except ** that it is named "<database>-oal" instead of "<database>-wal". ** Because regular SQLite clients do not look for file named ** "<database>-oal", they go on using the original database in ** rollback mode while the *-oal file is being generated. *** During this stage RBU does not update the database by writing ** directly to the target tables. Instead it creates "impostor" ** tables using the SQLITE_TESTCTRL_IMPOSTER interface that it uses ** to update each b-tree individually. All updates required by each ** b-tree are completed before moving on to the next, and all ** updates are done in sorted key order. *** 2) The "<database>-oal" file is moved to the equivalent "<database>-wal" ** location using a call to rename(2). Before doing this the RBU ** module takes an EXCLUSIVE lock on the database file, ensuring ** that there are no other active readers. *** Once the EXCLUSIVE lock is released, any other database readers ** detect the new *-wal file and read the database in wal mode. At ** this point they see the new version of the database - including ** the updates made as part of the RBU update. *** 3) The new *-wal file is checkpointed. This proceeds in the same way ** as a regular database checkpoint, except that a single frame is ** checkpointed each time sqlite3rbu_step() is called. If the RBU ** handle is closed before the entire *-wal file is checkpointed, ** the

checkpoint progress is saved in the RBU database and the ** checkpoint can be resumed by another RBU client at some point in ** the future. *** POTENTIAL PROBLEMS *** The rename() call might not be portable. And RBU is not currently ** syncing the directory after renaming the file. *** When state is saved, any commit to the *-oal file and the commit to ** the RBU update database are not atomic. So if the power fails at the ** wrong moment they might get out of sync. As the main database will be ** committed before the RBU update database this will likely either just ** pass unnoticed, or result in SQLITE_CONSTRAINT errors (due to UNIQUE ** constraint violations). *** If some client does modify the target database mid RBU update, or some ** other error occurs, the RBU extension will keep throwing errors. It's ** not really clear how to get out of this state. The system could just ** by delete the RBU update database and *-oal file and have the device ** download the update again and start over. *** At present, for an UPDATE, both the new.* and old.* records are ** collected in the rbu_xyz table. And for both UPDATES and DELETES all ** fields are collected. This means we're probably writing a lot more ** data to disk when saving the state of an ongoing update to the RBU ** update database than is strictly necessary. ***

75485. out2: P2 is an output

75486. The JSON parser that contains the TARGET

75487. Join type mask

75488. 1 byte past end of aAll

75489. porter rule condition: (*v*)

75490. Number of tokens desired for snippet

75491. True if sorter record includes seq. no.

75492. int

75493. Set the output variables before returning.

75494. First argument to sqlite3_result_...()

75495. ** This constant should already be defined (in the "WinNT.h" SDK file).

75496. Index in mem3.aPool[] of next free chunk

75497. Set variable iNext to the next available segdir index at level iLevel.

75498. xBestIndex - Determine search strategy

75499. Where to jump when NULLs seen in step 2

75500. Require a write-lock on the table to perform this operation

75604. True if opening an ephemeral, temporary database

75605. ** This is the xFilter interface for the virtual table. See ** the virtual table xFilter method documentation for additional ** information. ** ** There are three possible query strategies: ** ** 1. Full-text search using a MATCH operator. ** 2. A by-rowid lookup. ** 3. A full-table scan.

75606. First register in VUpdate arg array

75607. in1

75608. The write cursors opened by WHERE_ONEPASS

75609. ** Populate pCsr->aMatchinfo[] with data for the current row. The ** 'matchinfo' data is an array of 32-bit unsigned integers (C type u32).

75610. X==Ei (form A) or just Ei (form B)

75611. Array used to calculate phrase freq.

75612. Index of loop to report on

75613. IN/OUT: SegmentWriter handle

75614. Root page of index

75615. ** 2001 September 15 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** This header file defines the interface that the sqlite page cache ** subsystem. The page cache subsystem reads and writes a file a page ** at a time and provides a journal for rollback.

75616. Move the page to the head of the dirty list. If p->pDirtyPrev==0, ** then page p is already at the head of the dirty list and the ** following call would be a no-op. Hence the OPTIMIZATION-IF-FALSE ** tag above.

75617. EVIDENCE-OF: R-25451-61125 The SQLITE_CONFIG_URI option takes a single ** argument of type int. If non-zero, then URI handling is globally ** enabled. If the parameter is zero, then URI handling is globally ** disabled.

75618. Seg-reader cursor for this term

75619. Preserve SQL text

75620. This strategy involves a two rowid lookups on an B-Tree structures ** and then a linear search of an R-Tree node. This should be ** considered almost as quick as a direct rowid lookup (for which ** sqlite uses an internal cost of 0.0). It is expected to return ** a single row.

75621. !defined(SQLITE_RTREE_INT_ONLY)

75622. Version 3.18.0 and later

75623. Tokenizer object

75624. ** Return true if the iterator passed as the only argument is at EOF.

75625. a: p0<<14 | p2 (masked)

75626. Used by DOCID_CMP() macro

75627. Name of new table or NULL

75628. ** This routine implements a busy callback that sleeps and tries ** again until a timeout value is reached. The timeout value is ** an integer number of milliseconds passed in as the first ** argument.

75629. ** CAPI3REF: Register A Virtual Table Implementation ** METHOD: sqlite3 ** ** ^These routines are used to register a new [virtual table module] name. ** ^Module names must be registered before ** creating a new [virtual table] using the module and before using a ** preexisting [virtual table] for the module. ** ** ^The module name is registered on the [database connection] specified ** by the first parameter. ^The name of the module is given by the ** second parameter. ^The third parameter is a pointer to ** the implementation of the [virtual table module]. ^The fourth ** parameter is an arbitrary client data pointer that is passed through ** into the [xCreate] and [xConnect] methods of the virtual table module ** when a new virtual table is being created or reinitialized. ** ** ^The sqlite3_create_module_v2() interface has a fifth parameter which ** is a pointer to a destructor for the pClientData. ^SQLite will ** invoke the destructor function (if it is not NULL) when SQLite ** no longer needs the pClientData pointer. ^The destructor will also ** be invoked if the call to sqlite3_create_module_v2() fails. ** ^The sqlite3_create_module() ** interface is equivalent to sqlite3_create_module_v2() with a NULL ** destructor.

75630. !SQLITE_OS_WINCE && !SQLITE_OS_WINRT && SQLITE_WIN32_USE_UUID

75631. For an in-memory database, make sure the original page continues ** to exist, in case the transaction needs to roll back. Use pPgOld ** as the original page since it has already been allocated.

75632. aDistance array

75633. m

75634. ** PRAGMA [schema.]page_size ** PRAGMA [schema.]page_size=N ** ** The first form reports the current setting for the ** database page size in bytes. The second form sets the ** database page size value. The value can only be set if ** the database has not yet been created.

75635. Update statement to modify idx values

75636. Divider cells in pParent

75637. ** Clear any and all virtual-table information from the Table record. ** This routine is called, for example, just before deleting the Table ** record. ** ** Since it is a virtual-table, the Table structure contains a pointer ** to the head of a linked list of VTable structures. Each VTable ** structure is associated with a single sqlite3* user of the schema. ** The reference count of the VTable structure associated with database ** connection db is decremented immediately (which may lead to the ** structure being xDisconnected and free). Any other VTable structures ** in the list are moved to the sqlite3.pDisconnect list of the associated ** database connection.

75638. ** Maximum number of pages in one database file. ** ** This is really just the default value for the max_page_count pragma. ** This value can be lowered (or raised) at run-time using that the ** max_page_count macro.

75639. ** Deallocate all memory associated with a WhereAndInfo object.

75640. Absolute level to open

75641. Loop through all columns of the table being considered for snippets. ** If the iCol argument to this function was negative, this means all ** columns of the FTS3 table. Otherwise, only column iCol is considered.

75642. The expression to be fixed to one database

75643. Current size of wal-index file

75644. **comment:** ** If we get to this point, the path name should almost certainly be a purely ** relative one (i.e. not a UNC name, not absolute, and not volume relative).
label: code-design

75645. * This is the extra space for the initial size of the Win32-specific heap, * in bytes. This value may be zero.

75646. Minimum cell size is 4

75647. FILETIME structure is a 64-bit value representing the number of 100-nanosecond intervals since January 1, 1601 (= JD 2305813.5).

75648. Look for a valid schema=? constraint. If found, change the idxNum to ** 1 and request the value of that constraint be sent to xFilter. And ** lower the cost estimate to encourage the constrained version to be ** used.

75649. If an error has occurred, mark the session object as failed.

75650. Bitmask identifying table iTab

75651. Registers to allocate

75652. New rowid

75653. **comment:** Do not code a test for this constraint
label: test

75654. True if really sorted (not just grouped)

75655. One less than frame number of aPgn[1]

75656. Do not gather statistics on views or virtual tables

75657. Delete the master journal file. This commits the transaction. After ** doing this the directory is synced again before any individual ** transaction files are deleted.

75658. Buffer to fold text into

75659. ** Convert a UTF-16 string in the native encoding into a UTF-8 string. ** Memory to hold the UTF-8 string is obtained from sqlite3_malloc and must ** be freed by the calling function. ** ** NULL is returned if there is an allocation error.

75660. xFilter

75661. Could not find an existing table or index to use as the RHS b-tree. ** We will have to generate an ephemeral table to do the job.

75662. True if the AUTOINCREMENT keyword is present

75663. xColumn

75664. ** Retry ftruncate() calls that fail due to EINTR ** ** All calls to ftruncate() within this file should be made through ** this wrapper. On the Android platform, bypassing the logic below ** could lead to a corrupt database.

75665. ** Compare two ExprList objects. Return 0 if they are identical and ** non-zero if they differ in any way. ** ** If any subelement of pB has Expr.iTable==(-1) then it is allowed ** to compare equal to an equivalent element in pA with Expr.iTable==iTab. ** ** This routine might return non-zero for equivalent ExprLists. The ** only consequence will be disabled optimizations. But this routine ** must never return 0 if the two ExprList objects are different, or ** a malfunction will result. ** ** Two NULL pointers are considered to be the same. But a NULL pointer ** always differs from a non-NUL pointer.

75666. Base class. Must be first

75667. A-overwrites-OP

75668. Size decreases

75669. All threads share a single random number generator. ** This structure is the current state of the generator.

75670. Initial root node

75704. Number of entries in a[]

75705. The name context used to resolve the name

75706. SQLITE_ERROR

75707. Allocate a bitvec to use to store the set of pages rolled back

75708. Offset into aPrefix[] of the prefix string

75709. Pointer to value 2

75710. Array of child nodes

75711. ** CAPI3REF: String Comparison *** ^The [sqlite3_stricmp()] and [sqlite3_strnicmp()] APIs allow applications ** and extensions to compare the contents of two buffers containing UTF-8 ** strings in a case-independent fashion, using the same definition of "case ** independence" that SQLite uses internally when comparing identifiers.

75712. ** Do various sanity checks on a single page of a tree. Return ** the tree depth. Root pages return 0. Parents of root pages ** return 1, and so forth. *** These checks are done: ** ** 1. Make sure that cells and freeblocks do not overlap ** but combine to completely cover the page. ** 2. Make sure integer cell keys are in order. ** 3. Check the integrity of overflow pages. ** 4. Recursively call checkTreePage on all children. ** 5. Verify that the depth of all children is the same.

75713. The OR-clause broken out into subterms

75714. ** Deregister and destroy an RBU vfs created by an earlier call to ** sqlite3rbu_create_vfs().

75715. ** Possible values for the sqlite3.flags. ** ** Value constraints (enforced via assert()): ** SQLITE_FullFSync == PAGER_FULLFSYNC **
SQLITE_CkptFullFSync == PAGER_CKPT_FULLFSYNC ** SQLITE_CacheSpill == PAGER_CACHE_SPILL

75716. Make a copy of the entire SELECT statement that defines the view. ** This will force all the Expr.token.z values to be dynamically ** allocated rather than point to the input string - which means that ** they will persist after the current sqlite3_exec() call returns.

75717. adjust the sign of significand

75718. Table column number

75719. 660

75720. If MEM_Dyn is set then Mem.xDel!=0. ** Mem.xDel might not be initialized if MEM_Dyn is clear.

75721. Database structure for this iterator

75722. ** Only set the lastErrno if the error code is a real error and not ** a normal expected return code of SQLITE_BUSY or SQLITE_OK

75723. Note: the calls to BtreeKeyFetch() and DataFetch() below assert() ** that both the BtShared and database handle mutexes are held.

75724. ** FTS maintains a separate indexes for each language-id (a 32-bit integer). ** Within each language id, a separate index is maintained to store the ** document terms, and each configured prefix size (configured the FTS ** "prefix=" option). And each index consists of multiple levels ("relative ** levels"). ** ** All three of these values (the language id, the specific index and the ** level within the index) are encoded in 64-bit integer values stored ** in the %_segdir table on disk. This function is used to convert three ** separate component values into the single 64-bit integer value that ** can be used to query the %_segdir table. *** Specifically, each language-id/index combination is allocated 1024 ** 64-bit integer level values ("absolute levels"). The main terms index ** for language-id 0 is allocate values 0-1023. The first prefix index ** (if any) for language-id 0 is allocated values 1024-2047. And so on. ** Language 1 indexes are allocated immediately following language 0. ** ** So, for a system with nPrefix prefix indexes configured, the block of ** absolute levels that corresponds to language-id iLangid and index ** iIndex starts at absolute level ((iLangid * (nPrefix+1) + iIndex) * 1024).

75725. ** Return TRUE if a KeyInfo object can be change. The KeyInfo object ** can only be changed if this is just a single reference to the object. ** ** This routine is used only inside of assert() statements.

75726. **comment:** ** Open an RBU handle to perform an RBU vacuum on database file zTarget. ** An RBU vacuum is similar to SQLite's built-in VACUUM command, except ** that it can be suspended and resumed like an RBU update. ** ** The second argument to this function identifies a database in which ** to store the state of the RBU vacuum operation if it is suspended. The ** first time sqlite3rbu_vacuum() is called, to start an RBU vacuum ** operation, the state database should either not exist or be empty ** (contain no tables). If an RBU vacuum is suspended by calling ** sqlite3rbu_close() on the RBU handle before sqlite3rbu_step() has ** returned SQLITE_DONE, the vacuum state is stored in the state database. ** The vacuum can be resumed by calling this function to open a new RBU ** handle specifying the same target and state databases. ** ** If the second argument passed to this function is NULL, then the ** name of the state database is " <database>-vacuum", where <database> ** is the name of the target database file. In this case, on UNIX, if the ** state database is not already present in the file-system, it is created ** with the same permissions as the target db is made. ** ** This function does not delete the state database after an RBU vacuum ** is completed, even if it created it. However, if the call to ** sqlite3rbu_close() returns any value other than SQLITE_OK, the contents ** of the state tables within the state database are zeroed. This way, ** the next call to sqlite3rbu_vacuum() opens a handle that starts a ** new RBU vacuum operation. ** ** As with sqlite3rbu_open(), Zipvfs users should rever to the comment ** describing the sqlite3rbu_create_vfs() API function below for ** a description of the complications associated with using RBU with ** zipvfs databases.

75784. ** The zeroblob(N) function returns a zero-filled blob of size N bytes.
75785. Invalidate all ephemeral cursor row caches
75786. Generate code to skip over the creation and initialization of the ** transient index on 2nd and subsequent iterations of the loop.
75787. ** If a Win32 native heap has been configured, this function will attempt to ** compact it. Upon success, SQLITE_OK will be returned. Upon failure, one ** of SQLITE_NOMEM, SQLITE_ERROR, or SQLITE_NOTFOUND will be returned. The ** "pnLargest" argument, if non-zero, will be used to return the size of the ** largest committed free block in the heap, in bytes.
75788. "rowid" column of stat[34] entry
75789. duplicate the FROM clause as it is needed by both the DELETE/UPDATE tree ** and the SELECT subtree.
75790. 250
75791. ASC or DESC for INTEGER PRIMARY KEY
75792. The pSubWInfo->untestedTerms flag means that this OR term ** contained one or more AND term from a notReady table. The ** terms from the notReady table could not be tested and will ** need to be tested later.
75793. Operation performed by this node
75794. Which column of the vector to return
75795. Comparison result if keys are equal
75796. Write the averages record
75797. ** Set the SegReader to point to the first docid in the doclist associated ** with the current term.
75798. Obtain a RESERVED lock on the database file. If the exFlag parameter ** is true, then immediately upgrade this to an EXCLUSIVE lock. The ** busy-handler callback can be used when upgrading to the EXCLUSIVE ** lock, but not when obtaining the RESERVED lock.
75799. TEMPORARY
75800. True if there is a doclist-index
75801. Used to iterate name contexts
75802. The routine to run as a thread
75803. ** If the following global variable points to a string which is the ** name of a directory, then that directory will be used to store ** all database files specified with a relative pathname. ** ** See also the "PRAGMA data_store_directory" SQL command.
75804. Database only autoinc table
75805. Now begin substituting subquery result set expressions for ** references to the iParent in the outer query. ** ** Example: ** ** SELECT a+5, b*10 FROM (SELECT x*3 AS a, y+10 AS b FROM t1) WHERE a>b; ** ______ subquery ______ / ** ______ outer query

/ ** ** We look at every expression in the outer query and every place we see ** "a" we substitute "x*3" and every place we see "b" we substitute "y+10".
75806. Mask of FTSS5INDEX_QUERY_X flags
75807. True if callback data is initialized
75808. automatically defined by SQLITE_ENABLE_FTS4
75809. The ONEPASS_DESIRED flags never occurs together with ORDER BY
75810. Text of the error report
75811. Number of bytes in string zName
75812. OUT: Number of phrases in query
75813. Compute collating sequences used by ** temporary tables needed to implement the compound select. ** Attach the KeyInfo structure to all temporary tables. **
** This section is run by the right-most SELECT statement only. ** SELECT statements to the left always skip this part. The right-most ** SELECT might also skip this part if it has no ORDER BY clause and ** no temp tables are required.
75814. Forward reference
75815. WITH => ID
75816. ** Allocate a new porter tokenizer. Return a pointer to the new ** tokenizer in *ppModule
75817. SQL-style comments from "--" to end of line
75818. Return the size of an allocation
75819. **comment:** ** Allocate memory that is to be used and released right away. ** This routine is similar to alloca() in that it is not intended ** for situations where the memory might be held long-term. This ** routine is intended to get memory to old large transient data ** structures that would not normally fit on the stack of an ** embedded processor.
label: code-design

75820. ** Generate code for the SELECT statement given in the p argument. *** The results are returned according to the SelectDest structure. ** See comments in sqliteInt.h for further information. *** This routine returns the number of errors. If any errors are ** encountered, then an appropriate error message is left in ** pParse->zErrMsg. *** This routine does NOT free the Select structure passed in. The ** calling function needs to do that.

75821. ** Constants used for locking

75822. Reference page

75823. ** Return TRUE if zTable is the name of the system table that stores the ** list of users and their access credentials.

75824. ** Open an RBU handle. *** Argument zTarget is the path to the target database. Argument zRbu is ** the path to the RBU database. Each call to this function must be matched ** by a call to sqlite3rbu_close(). When opening the databases, RBU passes ** the SQLITE_CONFIG_URI flag to sqlite3_open_v2(). So if either zTarget ** or zRbu begin with "file:", it will be interpreted as an SQLite ** database URI, not a regular file name. *** If the zState argument is passed a NULL value, the RBU extension stores ** the current state of the update (how many rows have been updated, which ** indexes are yet to be updated etc.) within the RBU database itself. This ** can be convenient, as it means that the RBU application does not need to ** organize removing a separate state file after the update is concluded. ** Or, if zState is non-NULL, it must be a path to a database file in which ** the RBU extension can store the state of the update. *** When resuming an RBU update, the zState argument must be passed the same ** value as when the RBU update was started. *** Once the RBU update is finished, the RBU extension does not ** automatically remove any zState database file, even if it created it. *** By default, RBU uses the default VFS to access the files on disk. To ** use a VFS other than the default, an SQLite "file:" URI containing a ** "vfs=..." option may be passed as the zTarget option. *** IMPORTANT NOTE FOR ZIPVFS USERS: The RBU extension works with all of ** SQLite's built-in VFSs, including the multiplexor VFS. However it does ** not work out of the box with zipvfs. Refer to the comment describing ** the zipvfs_create_vfs() API below for details on using RBU with zipvfs.

75825. ** The second argument is a Trigger structure allocated by the ** fkActionTrigger() routine. This function deletes the Trigger structure ** and all of its sub-components. *** The Trigger structure or any of its sub-components may be allocated from ** the lookaside buffer belonging to database handle dbMem.

75826. Current node image to append to

75827. True if next rowid is first in page

75828. Update the db file change counter via the direct-write method. The ** following call will modify the in-memory representation of page 1 ** to include the updated change counter and then write page 1 ** directly to the database file. Because of the atomic-write ** property of the host file-system, this is safe.

75829. OUT: True if there are NULL values in PK

75830. FTS5 backend object

75831. Return SQLITE_ROW

75832. same as TK_STRING, out2

75833. Previous id read from aDoclist

75834. RAISE

75835. The page of the frame to be written

75836. Used to iterate through phrase tokens

75837. Name of database file for pPager

75838. The VDBE under construction

75839. The row that the VUpdate opcode will delete: none

75840. ** Define the parameters of the hash tables in the wal-index file. There ** is a hash-table following every HASHTABLE_NPAGE page numbers in the ** wal-index. *** Changing any of these constants will alter the wal-index format and ** create incompatibilities.

75841. Append a single character

75842. Fts5Storage.aTotalSize[]

75843. Start the view context

75844. (315) foreach_clause ::=

75845. True if RHS must be unique

75846. For STRING expressions, the near cluster

75847. ***** End of fault.c *****

75848. Value to return via *paiCol

75849. If SQLITE_FTS5_ENABLE_TEST_MI is defined, assume that the file ** fts5_test_mi.c is compiled and linked into the executable. And call ** its entry point to enable the matchinfo() demo.

75850. zName

75851. Check for a "special" INSERT operation. One of the form: *** INSERT INTO xyz(xyz) VALUES('command');

75852. UPDATE + DELETE

75853. Cannot be both MEM_Null and some other type

75854. No rowid. PRIMARY KEY is the key

75855. in3

75856. ** If the TRANSLATE_TRACE macro is defined, the value of each Mem is ** printed on stderr on the way into and out of sqlite3VdbeMemTranslate().

75857. IGNORE

75858. ** This function is invoked by the vdbe to call the xDestroy method ** of the virtual table named zTab in database iDb. This occurs ** when a DROP TABLE is mentioned. *** This call is a no-op if zTab is not a virtual table.

75859. 0x01

75860. Parent frame

75861. Used to iterate through aHash[]

75862. STAT3 and STAT4 have a parameter on this routine.

75863. CONSTRAINT

75864. ** Argument pNode is an FTS5_AND node.

75865. assert(db->pPreUpdate->pUnpacked);

75866. Address of OP_FkIfZero

75867. ** Recompute pMerger->aTree[iOut] by comparing the next keys on the ** two PmaReaders that feed that entry. Neither of the PmaReaders ** are advanced. This routine merely does the comparison.

75868. xShutdown

75869. 3-byte signed integer

75870. This is the sub-WHERE clause body. First skip over ** duplicate rows from prior sub-WHERE clauses, and record the ** rowid (or PRIMARY KEY) for the current row so that the same ** row will be skipped in subsequent sub-WHERE clauses.

75871. Create an implicit NOT operator.

75872. ** json_array_length(JSON) ** json_array_length(JSON, PATH) ** ** Return the number of elements in the top-level JSON array. ** Return 0 if the input is not a well-formed JSON array.

75873. Two copies of the header content

75874. Program counter

75875. Allocate the Fts5Bm25Data object

75876. If there is no more data to be read from the buffer, read the next ** p->nBuffer bytes of data from the file into it. Or, if there are less ** than p->nBuffer bytes remaining in the PMA, read all remaining data.

75877. ** Rtree virtual table module xFilter method.

75878. Visibility of parent node

75879. ** Read an entry from the pointer map. *** This routine retrieves the pointer map entry for page 'key', writing ** the type and parent page number to *pEType and *pPgno respectively. ** An error code is returned if something goes wrong, otherwise SQLITE_OK.

75880. Remove page from cache

75881. Cursor number of the subquery

75882. SELECT may not have a LIMIT clause

75883. Beginning here are the reduction cases. A typical example ** follows: ** case 0: ** #line <lineno> <grammarfile> ** { ... } // User supplied code ** #line <lineno> <thisfile> ** break;

75884. ** Attempt to seek the file-descriptor passed as the first argument to ** absolute offset iOff, then attempt to write nBuf bytes of data from ** pBuf to it. If an error occurs, return -1 and set *piErrno. Otherwise, ** return the actual number of bytes written (which may be less than ** nBuf).

75885. End mark for a varint

75886. If RESTRICT, "SELECT RAISE(...)"

75887. Open the index sub-system

75888. ** Convert a scalar expression node to a TK_REGISTER referencing ** register iReg. The caller must ensure that iReg already contains ** the correct value for the expression.

75889. Uncommitted Hash table changes

75890. ** An instance of the following structure holds information about SQL ** functions arguments that are the parameters to the printf() function.

75891. Set the P5 operand of the OP_Program instruction to non-zero if ** recursive invocation of this trigger program is disallowed. Recursive ** invocation is disallowed if (a) the sub-program is really a trigger, ** not a foreign key action, and (b) the flag to enable recursive triggers ** is clear.

75892. Subtask context (for pKeyInfo)

75893. The pBt is no longer on the sharing list, so we can access ** it without having to hold the mutex. ** ** Clean out and delete the BtShared object.

75894. OUT: SQLite db handle

75895. Opcode: AutoCommit P1 P2 * * * ** Set the database auto-commit flag to P1 (1 or 0). If P2 is true, roll ** back any currently active btree transactions. If there are any active ** VMs (apart from this one), then a ROLLBACK fails. A COMMIT fails if ** there are active writing VMs or active VMs that use shared cache. ** ** This instruction causes the VM to halt.

75896. Has no NOT INDEXED clause

75897. **comment:** Convert the data in the temporary table into whatever form ** it is that we currently need.
label: code-design

75944. ** Combine two changesets together.

75945. OUT: Total number of OR nodes in expr.

75946. Object partially overlaps query region

75947. ** RECORD FORMAT: *** The following record format is similar to (but not compatible with) that ** used in SQLite database files. This format is used as part of the ** change-set binary format, and so must be architecture independent. *** Unlike the SQLite database record format, each field is self-contained - ** there is no separation of header and data. Each field begins with a ** single byte describing its type, as follows: *** 0x00: Undefined value. ** 0x01: Integer value. ** 0x02: Real value. ** 0x03: Text value. ** 0x04: Blob value. ** 0x05: SQL NULL value. *** Note that the above match the definitions of SQLITE_INTEGER, SQLITE_TEXT ** and so on in sqlite3.h. For undefined and NULL values, the field consists ** only of the single type byte. For other types of values, the type byte ** is followed by: *** Text values: ** A varint containing the number of bytes in the value (encoded using ** UTF-8). Followed by a buffer containing the UTF-8 representation ** of the text value. There is no nul terminator. *** Blob values: ** A varint containing the number of bytes in the value, followed by ** a buffer containing the value itself. *** Integer values: ** An 8-byte big-endian integer value. *** Real values: ** An 8-byte big-endian IEEE 754-2008 real value. *** Varint values are encoded in the same way as varints in the SQLite ** record format. *** CHANGESET FORMAT: *** A changeset is a collection of DELETE, UPDATE and INSERT operations on ** one or more tables. Operations on a single table are grouped together, ** but may occur in any order (i.e. deletes, updates and inserts are all ** mixed together). *** Each group of changes begins with a table header: *** 1 byte: Constant 0x54 (capital 'T') ** Varint: Number of columns in the table. ** nCol bytes: 0x01 for PK columns, 0x00 otherwise. ** N bytes: Unqualified table name (encoded using UTF-8). Null-terminated. *** Followed by one or more changes to the table. *** 1 byte: Either SQLITE_INSERT (0x12), UPDATE (0x17) or DELETE (0x09). ** 1 byte: The "indirect-change" flag. ** old.* record: (delete and update only) ** new.* record: (insert and update only) *** The "old." and "new." records, if present, are N field records in the ** format described above under "RECORD FORMAT", where N is the number of ** columns in the table. The i'th field of each record is associated with ** the i'th column of the table, counting from left to right in the order ** in which columns were declared in the CREATE TABLE statement. ** The new.* record that is part of each INSERT change contains the values ** that make up the new row. Similarly, the old.* record that is part of each ** DELETE change contains the values that made up the row that was deleted ** from the database. In the changeset format, the records that are part ** of INSERT or DELETE changes never contain any undefined (type byte 0x00) ** fields. *** Within the old.* record associated with an UPDATE change, all fields ** associated with table columns that are not PRIMARY KEY columns and are ** not modified by the UPDATE change are set to "undefined". Other fields ** are set to the values that made up the row before the UPDATE that the ** change records took place. Within the new.* record, fields associated ** with table columns modified by the UPDATE change contain the new ** values. Fields associated with table columns that are not modified ** are set to "undefined". *** PATCHSET FORMAT: *** A patchset is also a collection of changes. It is similar to a changeset, ** but leaves undefined those fields that are not useful if no conflict ** resolution is required when applying the changeset. *** Each group of changes begins with a table header: *** 1 byte: Constant 0x50 (capital 'P') ** Varint: Number of columns in the table. ** nCol bytes: 0x01 for PK columns, 0x00 otherwise. ** N bytes: Unqualified table name (encoded using UTF-8). Null-terminated. *** Followed by one or more changes to the table. *** 1 byte: Either SQLITE_INSERT (0x12), UPDATE (0x17) or DELETE (0x09). ** 1 byte: The "indirect-change" flag. ** single record: (PK fields for DELETE, PK and modified fields for UPDATE, ** full record for INSERT). *** As in the changeset format, each field of the single record that is part ** of a patchset change is associated with the correspondingly positioned ** table column, counting from left to right within the CREATE TABLE ** statement. *** For a DELETE change, all fields within the record except those associated ** with PRIMARY KEY columns are set to "undefined". The PRIMARY KEY fields ** contain the values identifying the row to delete. *** For an UPDATE change, all fields except those associated with PRIMARY KEY ** columns and columns that are modified by the UPDATE are set to "undefined". ** PRIMARY KEY fields contain the values identifying the table row to update, ** and fields associated with modified columns contain the new column values. *** The records associated with INSERT changes are in the same format as for ** changesets. It is not possible for a record associated with an INSERT ** change to contain a field set to "undefined".

75948. **comment:** ** Implementation of the sqlite3_pcache.xFetch method. *** Fetch a page by key value. ** ** Whether or not a new page may be allocated by this function depends on ** the value of the createFlag argument. 0 means do not allocate a new ** page. 1 means allocate a new page if space is easily available. 2 ** means to try really hard to allocate a new page. *** For a non-purgeable cache (a cache used as the storage for an in-memory ** database) there is really no difference between createFlag 1 and 2. So ** the calling function (pcache.c) will never have a createFlag of 1 on ** a non-purgeable cache. *** There are three different approaches to obtaining space for a page, ** depending on the value of parameter createFlag (which may be 0, 1 or 2). *** 1. Regardless of the value of createFlag, the cache is searched for a ** copy of the requested page. If one is found, it is returned. *** 2. If createFlag==0 and the page is not already in the cache, NULL is ** returned. *** 3. If createFlag is 1, and the page is not already in the cache, then ** return NULL (do not allocate a new page) if any of the following ** conditions are true: *** (a) the number of pages pinned by the cache is greater than ** PCache1.nMax, or *** (b) the number of pages pinned by the cache is greater than ** the sum of nMax for all purgeable caches, less the sum of ** nMin for all other purgeable caches, or *** 4. If none of the first three conditions apply and the cache is marked ** as purgeable, and if one of the following is true: *** (a) The number of pages allocated for the cache is already ** PCache1.nMax, or *** (b) The number of pages allocated for all purgeable caches is ** already equal to or greater than the sum of nMax for all ** purgeable caches, *** (c) The system is under memory pressure and wants to avoid ** unnecessary pages cache entry allocations *** then attempt to recycle a page from the LRU list. If it is the right ** size, return the recycled buffer. Otherwise, free the buffer and ** proceed to step 5. *** 5. Otherwise, allocate and return a new page buffer. *** There are two versions of this routine. pcache1FetchWithMutex() is ** the general case. pcache1FetchNoMutex() is a faster implementation for ** the common case where pGroup->mutex is NULL. The pcache1Fetch() wrapper ** invokes the appropriate routine.

75957. xCurrentTimeInt64 (version 2)

75958. Allocate the sqlite data structure

75959. Number of bytes to allocate

75960. Size of doclist

75961. Original value of pNew->wsFlags

75962. **comment:** Update the Fts5PageWriter.term field.

label: code-design

75963. The cursor to be moved

75964. Encoding did not change

75965. Size of the journal file in bytes

75966. !defined(_OS_COMMON_H_)

75967. ** INSERT OR REPLACE a record into the %_data table.
75968. WHERE rowid ..
75969. File descriptor for sub-journal
75970. The iterator to advance by one position
75971. For use by extension VFS
75972. In an UPDATE operation, if this index is the PRIMARY KEY index ** of a WITHOUT ROWID table and there has been no change the ** primary key, then no collision is possible. The collision detection ** logic below can all be skipped.
75973. synopsis: if fkctr[P1]==0 goto P2
75974. **comment:** NB: The sqlite3OpcodeName() function is implemented by code created ** by the mkopcodeh.awk and mkopcodec.awk scripts which extract the ** information from the vdbe.c source text
label: code-design
75975. PRAGMA fullfsync=ON
75976. RO incr-blob open on %_data table
75977. Write cell size here
75978. **** This function appends an update change to the buffer (see the comments ** under "CHANGESET FORMAT" at the top of the file). An update change ** consists of: ** ** 1 byte: SQLITE_UPDATE (0x17) ** n bytes: old.* record (see RECORD FORMAT) ** m bytes: new.* record (see RECORD FORMAT) ** ** The SessionChange object passed as the third argument contains the ** values that were stored in the row when the session began (the old.* ** values). The statement handle passed as the second argument points ** at the current version of the row (the new.* values). ** ** If all of the old.* values are equal to their corresponding new.* value ** (i.e. nothing has changed), then no data at all is appended to the buffer. ** ** Otherwise, the old.* record contains all primary key values and the ** original values of any fields that have been modified. The new.* record ** contains the new values of only those fields that have been modified.
75979. ** Allocate k new pages. Reuse old pages where possible.
75980. ***** End of analyze.c *****
75981. True if second change is indirect
75982. fall thru
75983. ** Return the maximum amount of memory that has ever been ** checked out since either the beginning of this process ** or since the most recent reset.
75984. First token in coalesced phrase instance
75985. Set nDestTruncate to the final number of pages in the destination ** database. The complication here is that the destination page ** size may be different to the source page size. ** ** If the source page size is smaller than the destination page size, ** round up. In this case the call to sqlite3OsTruncate() below will ** fix the size of the file. However it is important to call ** sqlite3PagerTruncateImage() here so that any pages in the ** destination file that lie beyond the nDestTruncate page mark are ** journalled by PagerCommitPhaseOne() before they are destroyed ** by the file truncation.
75986. Position of last value written
75987. Byte offset of end of current token
75988. Like SRT_Fifo, but unique results only
75989. Opcode: DecrJumpZero P1 P2 * * * * * Synopsis: if (--r[P1]==0 goto P2) ** Register P1 must hold an integer. Decrement the value in P1 ** and jump to P2 if the new value is exactly zero.
75990. IMPLEMENTATION-OF: R-57228-12904 Invoking sqlite3_finalize() on a NULL ** pointer is a harmless no-op.
75991. ** Allocate a new segment-id for the structure pStruct. The new segment ** id must be between 1 and 65335 inclusive, and must not be used by ** any currently existing segment. If a free segment id cannot be found, ** SQLITE_FULL is returned. ** ** If an error has already occurred, this function is a no-op. 0 is ** returned in this case.
75992. Fall through into OP_NeedsTable
75993. term ::= STRING
75994. ** Additional bit values that can be ORed with an affinity without ** changing the affinity. ** ** The SQLITE_NOTNULL flag is a combination of NULLEQ and JUMPIFNULL. ** It causes an assert() to fire if either operand to a comparison ** operator is NULL. It is added to certain comparison operators to ** prove that the operands are always NOT NULL.
75995. DB Page containing root of this index
75996. True if this is the first term written
75997. Index in pSrc->a[] of first new slot
75998. (299) tconcomma ::=
75999. The Windows errno from the last I/O error
76000. The token that holds the name of the view
76001. Construct an expression node for a unary postfix operator
76002. ** One of the cells in node pNode is guaranteed to have a 64-bit ** integer value equal to iRowid. Return the index of this cell.
76003. Multi-segment-reader handle
76004. ** Invoke SQLITE_FCNTL_MMAP_SIZE based on the current value of szMmap.
76005. ** Try to provide a memory barrier operation, needed for initialization ** and also for the xShmBarrier method of the VFS in cases when SQLite is ** compiled without mutexes (SQLITE_THREADS=0).
76006. Integer value of left operand
76007. Previous in LRU list of unpinned pages
76008. Free allocated structure
76009. ** Set the Pager.xGet method for the appropriate routine used to fetch ** content from the pager.
76010. See the tool/mkopcodeh.tcl script for details
76011. Number of bytes to read
76012. Number of child nodes
76013. Write the record
76014. **comment:** Sort entries into the forest on the first test of a new batch. ** To save unnecessary work, only do this when the batch number changes.
label: code-design
76015. Deprecated
76016. COLLATE
76017. IN/OUT: The WHERE clause to add to
76018. pArg
76019. SQLITE_UPDATE, DELETE or INSERT
76020. Pointer to allocation
76021. ***** Begin file date.c *****
76022. Number of memory cells used so far
76023. CREATE => nothing
76024. Select a sub-task to sort and flush the current list of in-memory ** records to disk. If the sorter is running in multi-threaded mode, ** round-robin between the first (pSorter->nTask-1) tasks. Except, if ** the background thread from a sub-tasks previous turn is still running, ** skip it. If the first (pSorter->nTask-1) sub-tasks are all still busy, ** fall back to using the final sub-task. The first (pSorter->nTask-1) ** sub-tasks are preferred as they use background threads - the final ** sub-task uses the main thread.
76025. pPager->pFirst = 0;
76026. Shorthand for pTerm->eOperator
76027. restore the original locking context and pMethod then close it
76028. SQLITE_OS_UNIX && defined(SQLITE_MUTEX_PTHREADS)
76029. ** Iterator pIter currently points to the first rowid in a doclist. This ** function sets the iterator up so that iterates in reverse order through ** the doclist.
76030. neardist_opt ::= COMMA STRING
76031. ** Return true if a memory cell is not marked as invalid. This macro ** is for use inside assert() statements only.
76032. This is one term of an OR-optimization using the PRIMARY KEY of a ** WITHOUT ROWID table. No need for a separate index
76033. The "B" part of a "A AS B" phrase. zName is the "A"

76034. The new freeblock is at the beginning of the cell content area, *** so just extend the cell content area rather than create another *** freelist entry
76035. ** An SQL parser context. A copy of this structure is passed through ** the parser and down into all the parser action routine in order to ** carry around information that is global to the entire parse. *** The structure is divided into two parts. When the parser and code ** generate call themselves recursively, the first part of the structure ** is constant but the second part is reset at the beginning and end of ** each recursion. *** The nTableLock and aTableLock variables are only used if the shared-cache ** feature is enabled (if sqlite3Tsd()->useSharedData is true). They are ** used to store the set of table-locks required by the statement being ** compiled. Function sqlite3TableLock() is used to add entries to the ** list.
76036. ** Open an in-memory journal file.
76037. On OS X on an msdos filesystem, the inode number is reported ** incorrectly for zero-size files. See ticket #3260. To work ** around this problem (we consider it a bug in OS X, not SQLite) ** we always increase the file size to 1 by writing a single byte ** prior to accessing the inode number. The one byte written is ** an ASCII 'S' character which also happens to be the first byte ** in the header of every SQLite database. In this way, if there ** is a race condition such that another thread has already populated ** the first page of the database, no damage is done.
76038. ** Decrement the BtShared.nRef counter. When it reaches zero, ** remove the BtShared structure from the sharing list. Return ** true if the BtShared.nRef counter reaches zero and return ** false if it is still positive.
76039. True to enable triggers
76040. ** This routine sets the value to be returned by subsequent calls to ** sqlite3_changes() on the database handle 'db'.
76041. Acts as query when has one argument
76042. ** This function merges two sorted lists into a single sorted list. *** aLeft[] and aRight[] are arrays of indices. The sort key is ** aContent[aLeft[]] and aContent[aRight[]]. Upon entry, the following ** is guaranteed for all J < K: *** aContent[aLeft[J]] < aContent[aLeft[K]] ** aContent[aRight[J]] < aContent[aRight[K]] *** This routine overwrites aRight[] with a new (probably longer) sequence ** of indices such that the aRight[] contains every index that appears in ** either aLeft[] or the old aRight[] and such that the second condition ** above is still met. *** The aContent[aLeft[X]] values will be unique for all X. And the ** aContent[aRight[X]] values will be unique too. But there might be ** one or more combinations of X and Y such that ** aLeft[X] != aRight[Y] && aContent[aLeft[X]] == aContent[aRight[Y]] *** When that happens, omit the aLeft[X] and use the aRight[Y] index.
76043. Switch on the character-class of the first byte ** of the token. See the comment on the CC_ defines ** above.
76044. File descriptor to write to
76045. ** This is called during initialization to register the fts5_expr() scalar ** UDF with the SQLite handle passed as the only argument.
76046. Number of active VDBEs that read and write
76047. ** Destroy the part of winFile that deals with wince locks
76048. Number of active OP_VDestroy operations
76049. try to create all the intermediate directories
76050. OE_Abort, OE_Ignore, OE_Replace, or OE_None
76051. ** Delete all cached deferred doclists. Deferred doclists are cached ** (allocated) by the sqlite3Fts3CacheDeferredDoclists() function.
76052. True if is an aggregate function
76053. Allocate new SessionTable object.
76054. Error and awaiting close
76055. Original value of pNew->u.btree.nTop
76056. FTS5_MAX_SEGMENT is currently defined as 2000. So the following ** array is 63 elements, or 252 bytes, in size.
76057. Join all threads
76058. This is really OP_Noop and OP_Explain
76059. If recursive mutexes are not available, then we have to grow ** our own. This implementation assumes that pthread_equal() ** is atomic - that it cannot be deceived into thinking self ** and p->owner are equal if p->owner changes between two values ** that are not equal to self while the comparison is taking place. *** This implementation also assumes a coherent cache - that ** separate processes cannot read different values from the same ** address at the same time. If either of these two conditions ** are not met, then the mutexes will fail and problems will result.
76060. OUT: True to retry.
76061. Get an EXCLUSIVE lock on the database file. At this point it is ** important that a RESERVED lock is not obtained on the way to the ** EXCLUSIVE lock. If it were, another process might open the ** database file, detect the RESERVED lock, and conclude that the ** database is safe to read while this process is still rolling the ** hot-journal back. *** Because the intermediate RESERVED lock is not requested, any ** other process attempting to access the database file will get to ** this point in the code and fail to obtain its own EXCLUSIVE lock ** on the database file. *** Unless the pager is in locking_mode=exclusive mode, the lock is ** downgraded to SHARED_LOCK before this function returns.
76062. End switch over the format type
76063. Assume an indexed expression can always yield a NULL
76064. ** This function retrieves the doclist for the specified term (or term ** prefix) from the database.
76065. Advance iterator ctx.iter so that it points to the first coalesced ** phrase instance at or following position iBestStart.
76066. Name of rank and rowid columns
76067. ** Insert or replace a WhereLoop entry using the template supplied. *** An existing WhereLoop entry might be overwritten if the new template ** is better and has fewer dependencies. Or the template will be ignored ** and no insert will occur if an existing WhereLoop is faster and has ** fewer dependencies than the template. Otherwise a new WhereLoop is ** added based on the template. *** If pBuilder->pOrSet is not NULL then we care about only the ** prerequisites and rRun and nOut costs of the N best loops. That ** information is gathered in the pBuilder->pOrSet object. This special ** processing mode is used only for OR clause processing. *** When accumulating multiple loops (when pBuilder->pOrSet is NULL) we ** still might overwrite similar loops with the new template if the ** new template is better. Loops may be overwritten if the following ** conditions are met: *** (1) They have the same iTab. ** (2) They have the same iSortIdx. ** (3) The template has same or fewer dependencies than the current loop ** (4) The template has the same or lower cost than the current loop
76068. ** Return True if it is possible that pIndex might be useful in ** implementing the ORDER BY clause in pBuilder. *** Return False if pBuilder does not contain an ORDER BY clause or ** if there is no way for pIndex to be useful in implementing that ** ORDER BY clause.
76069. rowid == ?
76070. Node number of parent node
76071. Array of hash slots
76072. Jump over the subroutines
76073. **comment:** Avoid memory leak when malloc fails
 label: code-design
76074. If after trying to extract new entries from the header, nHdrParsed is ** still not up to p2, that means that the record has fewer than p2 ** columns. So the result will be either the default value or a NULL.
76075. 980
76076. Opcode to add sorter record to sorter
76077. ***** Begin file trigger.c *****
76078. 1250
76079. ** Return the column declaration type (if applicable) of the i'th column ** of the result set of SQL statement pStmt.
76080. EVIDENCE-OF: R-61006-08918 If the memory pointer is not NULL then the ** alternative memory allocator is engaged to handle all of SQLites ** memory allocation needs.
76081. Set of table index masks
76082. The query is a simple term lookup that matches at most one term in ** the index. All that is required is a straight hash-lookup. *** Because the stack address of pE may be accessed via the aElem pointer ** below, the "Fts3HashElem *pE" must be declared so that it is valid ** within this entire function, not just this "else{...}" block.
76083. pIdx is not a UNIQUE index
76084. EVIDENCE-OF: R-53367-43190 If either argument to this option is ** negative, then that argument is changed to its compile-time default. *** EVIDENCE-OF: R-34993-45031 The maximum allowed mmap size will be ** silently truncated if necessary so that it does not exceed the ** compile-time maximum mmap size set by the SQLITE_MAX_MMAP_SIZE ** compile-time option.
76085. Length of database filename - dbPath
76086. ** Database Format of R-Tree Tables ** ----- ** The data structure for a single virtual r-tree table is stored in three ** native SQLite tables declared as follows. In each case, the '%' character ** in the table name is replaced with the user-supplied name of the r-tree ** table. *** CREATE

TABLE %_node(nodeno INTEGER PRIMARY KEY, data BLOB) ** CREATE TABLE %_parent(nodeno INTEGER PRIMARY KEY, parentnode INTEGER) **
CREATE TABLE %_rowid(rowid INTEGER PRIMARY KEY, nodeno INTEGER) *** The data for each node of the r-tree structure is stored in the %_node **
table. For each node that is not the root node of the r-tree, there is ** an entry in the %_parent table associating the node with its parent. ** And for each row of
data in the table, there is an entry in the %_rowid ** table that maps from the entries rowid to the id of the node that it ** is stored on. *** The root node of an r-
tree always exists, even if the r-tree table is ** empty. The nodeno of the root node is always 1. All other nodes in the ** table must be the same size as the root
node. The content of each node ** is formatted as follows: *** 1. If the node is the root node (node 1), then the first 2 bytes ** of the node contain the tree depth
as a big-endian integer. ** For non-root nodes, the first 2 bytes are left unused. *** 2. The next 2 bytes contain the number of entries currently ** stored in the
node. *** 3. The remainder of the node contains the node entries. Each entry ** consists of a single 8-byte integer followed by an even number ** of 4-byte
coordinates. For leaf nodes the integer is the rowid ** of a record. For internal nodes it is the node number of a ** child page.

76087. **comment:** Execute assert() statements to ensure that the Vdbe.apCsr[] and ** Vdbe.aMem[] arrays have already been cleaned up.

label: code-design

76088. ** Return a checksum of all entries in the FTS index that correspond to ** language id iLangid. The checksum is calculated by XORing the checksums ** of each
individual entry (see fts3ChecksumEntry()) together. *** If successful, the checksum value is returned and *pRc set to SQLITE_OK. ** Otherwise, if an error
occurs, *pRc is set to an SQLite error code. The ** return value is undefined in this case.

76089. OUT: Results of parse

76090. WITH clause that pCte belongs to

76091. Possible values for RtreeConstraint.op

76092. Mark node i of pParse as being a child of iParent. Call recursively ** to fill in all the descendants of node i.

76093. Allocate the array of TermOffset iterators.

76094. CURRENT_TIME

76095. ** Allowed flags for the 3rd parameter to sqlite3FindInIndex().

76096. int *psz

76097. Releasing a pending lock

76098. Combination of the previous two

76099. ** Attempt to automatically detect the operating system and setup the ** necessary pre-processor macros for it.

76100. Prerequisites of the pExpr->pLeft

76101. ccons ::= DEFAULT term

76102. Index cursor

76103. **comment:** ** This function is called just before writing a set of frames to the log ** file (see sqlite3WalFrames()). It checks to see if, instead of appending ** to
the current log file, it is possible to overwrite the start of the ** existing log file with the new frames (i.e. "reset" the log). If so, ** it sets pWal->hdr.mxFrame to 0.
Otherwise, pWal->hdr.mxFrame is left ** unchanged. *** SQLITE_OK is returned if no error is encountered (regardless of whether ** or not pWal-
>hdr.mxFrame is modified). An SQLite error code is returned ** if an error occurs.

label: code-design

76105. ***** Include os_common.h in the middle of mutex_w32.c *****

76106. from ::= FROM seltablist

76107. IMP: R-26835-10964

76108. xOpen - open a cursor

76109. **comment:** ** This routine attempts to flatten subqueries as a performance optimization. ** This routine returns 1 if it makes changes and 0 if no flattening occurs.

*** To understand the concept of flattening, consider the following ** query: *** SELECT a FROM (SELECT x+y AS a FROM t1 WHERE z<100) WHERE
a>5 *** The default way of implementing this query is to execute the ** subquery first and store the results in a temporary table, then ** run the outer query on
that temporary table. This requires two ** passes over the data. Furthermore, because the temporary table ** has no indices, the WHERE clause on the outer query
cannot be ** optimized. *** This routine attempts to rewrite queries such as the above into ** a single flat select, like this: *** SELECT x+y AS a FROM t1
WHERE z<100 AND a>5 *** The code generated for this simplification gives the same result ** but only has to scan the data once. And because indices might
** exist on the table t1, a complete scan of the data might be ** avoided. *** Flattening is only attempted if all of the following are true: *** (1) The subquery
and the outer query do not both use aggregates. ** (2) The subquery is not an aggregate or (2a) the outer query is not a join ** and (2b) the outer query does not
use subqueries other than the one ** FROM-clause subquery that is a candidate for flattening. (2b is ** due to ticket [2f170d73bf9abf80] from 2015-02-09.) **
*** (3) The subquery is not the right operand of a LEFT JOIN ** or (a) the subquery is not itself a join and (b) the FROM clause ** of the subquery does not
contain a virtual table and (c) the ** outer query is not an aggregate. *** (4) The subquery is not DISTINCT. *** (**) At one point restrictions (4) and (5)
defined a subset of DISTINCT ** sub-queries that were excluded from this optimization. Restriction ** (4) has since been expanded to exclude all DISTINCT
subqueries. *** (6) The subquery does not use aggregates or the outer query is not ** DISTINCT. *** (7) The subquery has a FROM clause. TODO: For
subqueries without ** A FROM clause, consider adding a FROM clause with the special ** table sqlite_once that consists of a single row containing a ** single
NULL. *** (8) The subquery does not use LIMIT or the outer query is not a join. *** (9) The subquery does not use LIMIT or the outer query does not use **
aggregates. *** (**) Restriction (10) was removed from the code on 2005-02-05 but we ** accidentally carried the comment forward until 2014-09-15. Original
** text: "The subquery does not use aggregates or the outer query ** does not use LIMIT." *** (11) The subquery and the outer query do not both have ORDER
BY clauses. *** (**) Not implemented. Subsumed into restriction (3). Was previously ** a separate restriction deriving from ticket #350. *** (13) The
subquery and outer query do not both use LIMIT. *** (14) The subquery does not use OFFSET. *** (15) The outer query is not part of a compound select or
the ** subquery does not have a LIMIT clause. ** (See ticket #2339 and ticket [02a8e81d44].) *** (16) The outer query is not an aggregate or the subquery does
** not contain ORDER BY. (Ticket #2942) This used to not matter ** until we introduced the group_concat() function. *** (17) The sub-query is not a
compound select, or it is a UNION ALL ** compound clause made up entirely of non-aggregate queries, and ** the parent query: **** is not itself part of a
compound select, ** is not an aggregate or DISTINCT query, and ** is not a join ** ** The parent and sub-query may contain WHERE clauses. Subject to **
rules (11), (13) and (14), they may also contain ORDER BY, ** LIMIT and OFFSET clauses. The subquery cannot use any compound ** operator other than
UNION ALL because all the other compound ** operators have an implied DISTINCT which is disallowed by ** restriction (4). *** Also, each component of
the sub-query must return the same number ** of result columns. This is actually a requirement for any compound ** SELECT statement, but all the code here
does is make sure that no ** such (illegal) sub-query is flattened. The caller will detect the ** syntax error and return a detailed message. *** (18) If the sub-
query is a compound select, then all terms of the ** ORDER BY clause of the parent must be simple references to ** columns of the sub-query. *** (19) The
subquery does not use LIMIT or the outer query does not ** have a WHERE clause. *** (20) If the sub-query is a compound select, then it must not use ** an
ORDER BY clause. Ticket #3773. We could relax this constraint ** somewhat by saying that the terms of the ORDER BY clause must ** appear as unmodified
result columns in the outer query. But we ** have other optimizations in mind to deal with that case. *** (21) The subquery does not use LIMIT or the outer
query is not ** DISTINCT. (See ticket [752e1646fc].) *** (22) The subquery is not a recursive CTE. *** (23) The parent is not a recursive CTE, or the sub-
query is not a ** compound query. This restriction is because transforming the ** parent to a compound query confuses the code that handles ** recursive queries
in multiSelect(). *** (24) The subquery is not an aggregate that uses the built-in min() or ** or max() functions. (Without this restriction, a query like: **
"SELECT x FROM (SELECT max(y), x FROM t1)" would not necessarily ** return the value X for which Y was maximal.) *** In this routine, the "p"
parameter is a pointer to the outer query. ** The subquery is p->pSrc->a[ifFrom]. isAgg is true if the outer query ** uses aggregates and subqueryIsAgg is true if
the subquery uses aggregates. *** If flattening is not attempted, this routine is a no-op and returns 0. ** If flattening is attempted this routine returns 1. *** All
of the expression analysis must occur on both the outer query and ** the subquery before this routine runs.

label: code-design

76110. ** Implement a memory barrier or memory fence on shared memory. ** All loads and stores begun before the barrier must complete before ** any load or store
begun after the barrier.

76111. ** Return a pointer to the data for the specified page.

76112. ** The proxy locking method is a "super-method" in the sense that it ** opens secondary file descriptors for the conch and lock files and ** it uses proxy, dot-file,
AFP, and flock() locking methods on those ** secondary files. For this reason, the division that implements ** proxy locking is located much further down in the
file. But we need ** to go ahead and define the sqlite3_io_methods and finder function ** for proxy locking here. So we forward declare the I/O methods.

76113. Bytes of text in zName

76114. File descriptor open on db file

76115. If pLast is NULL at this point, then the last rowid for this doclist ** lies on the page currently indicated by the iterator. In this case ** pIter->iLeafOffset is already
set to point to the position-list size ** field associated with the first relevant rowid on the page. *** Or, if pLast is non-NULL, then it is the page that contains the
last ** rowid. In this case configure the iterator so that it points to the ** first rowid on this page.

76116. ** Return the number of connections to the BtShared object accessed by ** the Btree handle passed as the only argument. For private caches ** this is always 1.
For shared caches it may be 1 or greater.

76117. The BLOB encoding of the document size

76118. Next value in trailing position list

76119. Language id for tokenizer

76120. The "docid <= ?" constraint, if any

76121. If pToRelease is not zero than pPayload points into the data area ** of pToRelease. Make sure pToRelease is still writeable.

76122. ** Generate code that will do an analysis of a single table in ** a database. If pOnlyIdx is not NULL then it is a single index ** in pTab that should be analyzed.

76123. Opcode: NewRowid P1 P2 P3 * * *** Synopsis: r[P2]=rowid ** ** Get a new integer record number (a.k.a "rowid") used as the key to a table. ** The record number is not previously used as a key in the database ** table that cursor P1 points to. The new record number is written ** written to register P2. ** ** If P3>0 then P3 is a register in the root frame of this VDBE that holds ** the largest previously generated record number. No new record numbers are ** allowed to be less than this value. When this value reaches its maximum, ** an SQLITE_FULL error is generated. The P3 register is updated with the ** generated record number. This P3 mechanism is used to help implement the ** AUTOINCREMENT feature.

76124. Only the first key on the page may ==maxKey

76125. XISTSAVEPOINTERSECTTRIGGERREFERENCESCONSTRAINTOFFSETTEMPORARY

76126. Number of columns in the result

76127. Both sides of the comparison are columns. If one has numeric ** affinity, use that. Otherwise use no affinity.

76128. Number of entries in aEquiv[]

76129. "rank" function. Populated on demand from vtab.xColumn().

76130. ***** End of the posix advisory lock implementation *****

76131. A pure NULL might have other flags, such as MEM_Static, MEM_Dyn, ** MEM_Ephem, MEM_Cleared, or MEM_Subtype

76132. Array of mmap'd *-shm regions

76133. ** For the entry that cursor pCur is point to, return as ** many bytes of the key or data as are available on the local ** b-tree page. Write the number of available bytes into *pAmt. ** ** The pointer returned is ephemeral. The key/data may move ** or be destroyed on the next call to any Btree routine, ** including calls from other threads against the same cache. ** Hence, a mutex on the BtShared should be held prior to calling ** this routine. ** ** These routines is used to get quick access to key and data ** in the common case where no overflow pages are used.

76134. Query result set. Req'd for DISTINCT

76135. (314) plus_num ::= INTEGER|FLOAT

76136. ** zSql is a zero-terminated string of UTF-8 SQL text. Return the number of ** bytes in this text up to but excluding the first character in ** a host parameter. If the text contains no host parameters, return ** the total number of bytes in the text.

76137. The specific table containing the indexed database

76138. If not NULL, bind only if true

76139. ** Create a tokenizer cursor to tokenize an input buffer. The caller ** is responsible for ensuring that the input buffer remains valid ** until the cursor is closed (using the xClose() method).

76140. Estimated cost of using this index

76141. ** Masks used for mem5.aCtrl[] elements.

76142. The cursor on the LHS of the term

76143. ** Locate the table identified by *p. ** ** This is a wrapper around sqlite3LocateTable(). The difference between ** sqlite3LocateTable() and this function is that this function restricts ** the search to schema (p->pSchema) if it is not NULL. p->pSchema may be ** non-NULL if it is part of a view or trigger program definition. See ** sqlite3FixSrcList() for details.

76144. Zero tells OP_Found to use a composite key

76145. If either the iTab or iSortIdx values for two WhereLoop are different ** then those WhereLoops need to be considered separately. Neither is ** a candidate to replace the other.

76146. Size of header before each frame in wal

76147. !defined(SQLITE_VDBEINT_H)

76148. Database to be rekeyed

76149. Evaluate subqueries as coroutines

76150. Extra bytes at the end

76151. At this point the transaction is committed but the write lock ** is still held on the file. If there is a size limit configured for ** the persistent journal and the journal file currently consumes more ** space than that limit allows for, truncate it now. There is no need ** to sync the file following this operation.

76152. expr ::= CASE case_operand case_explist case_else END

76153. Value for "level" field (absolute level)

76154. Mask of usable tables

76155. True to allow FTS4-only syntax

76156. Generate code to handle the case of A>B

76157. Output buffer

76158. Absolute index of input segments

76159. ***** Interface to code in fts5_vocab.c.

76160. ** Make sure the BtCursor* given in the argument has a valid ** BtCursor.info structure. If it is not already valid, call ** btreeParseCell() to fill it in. ** ** BtCursor.info is a cache of the information in the current cell. ** Using this cache reduces the number of calls to btreeParseCell().

76161. ***** End of table.c *****

76162. **comment:** ***** The cases of the switch statement above this line should all be indented ** by 6 spaces. But the left-most 6 spaces have been removed to improve the ** readability. From this point on down, the normal indentation rules are ** restored. *****

76163. ** Generate the text of a WHERE expression which can be used to select all ** temporary triggers on table pTab from the sqlite_temp_master table. If ** table pTab has no temporary triggers, or is itself stored in the ** temporary database, NULL is returned.

76164. EVIDENCE-OF: R-59310-51205 The "reserved space" size in the 1-byte ** integer at offset 20 is the number of bytes of space at the end of ** each page to reserve for extensions. ** ** EVIDENCE-OF: R-37497-42412 The size of the reserved region is ** determined by the one-byte unsigned integer found at an offset of 20 ** into the database file header.

This may involve deleting entries from the %_segments ** table, and modifying existing entries in both the %_segments and %_segdir ** tables. ** * SQLITE_OK is returned if the segment is updated successfully. Or an ** SQLite error code otherwise.
76392. ** Routines to read or write a two- and four-byte big-endian integer values.
76393. #include "fts3_tokenizer.h"
76394. ** Empty (but do not delete) a hash table.
76395. ** Add type and collation information to a column list based on ** a SELECT statement. ** * The column list presumably came from selectColumnNamesFromExprList(). ** The column list has only names, not types or collations. This ** routine goes through and adds the types and collations. ** ** This routine requires that all identifiers in the SELECT ** statement be resolved.
76396. ** Attempt to parse the given string into a julian day number. Return ** the number of errors. ** * The following are acceptable forms for the input string: ** * * * YYYY-MM-DD HH:MM:SS.FFF +/-HH:MM ** DDDD.DD ** now ** * * In the first form, the +/-HH:MM is always optional. The fractional ** seconds extension (the ".FFF") is optional. The seconds portion ** ("::SS.FFF") is option. The year and date can be omitted as long ** as there is a time string. The time string can be omitted as long ** as there is a year and date.
76397. File path associated with error
76398. This array determines which meta meta values are preserved in the ** vacuum. Even entries are the meta value number and odd entries ** are an increment to apply to the meta value after the vacuum. ** The increment is used to increase the schema cookie so that other ** connections to the same database will know to reread the schema.
76399. ** 2013 Apr 22 ** * * The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** * * May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This file contains code for the "fts3tokenize" virtual table module. ** An fts3tokenize virtual table is created as follows: ** * * CREATE VIRTUAL TABLE <tbl> USING fts3tokenize(** <tokenizer-name>, <arg-1>, ...); ** * * The table created has the following schema: ** * * CREATE TABLE <tbl>(input, token, start, end, position) ** * * When queried, the query must include a WHERE clause of type: ** * * input = <string> ** * * The virtual table module tokenizes this <string>, using the FTS3 ** tokenizer specified by the arguments to the CREATE VIRTUAL TABLE ** statement and returns one row for each token in the result. With ** fields set as follows: ** * * input: Always set to a copy of <string> ** token: A token from the input. ** start: Byte offset of the token within the input <string>. ** end: Byte offset of the byte immediately following the end of the ** token within the input string. ** pos: Token offset of token within input. **
76400. Read and decode the next log frame.
76401. Pointer to 1 byte past end of doclist
76402. Memory cell containing record
76403. ** This function is a no-op if *pRc is other than SQLITE_OK when it is called. ** Otherwise, it advances the expression passed as the second argument to ** point to the next matching row in the database. Expressions iterate through ** matching rows in docid order. Ascending order if Fts3Cursor.bDesc is zero, ** or descending if it is non-zero. ** * * If an error occurs, *pRc is set to an SQLite error code. Otherwise, if ** successful, the following variables in pExpr are set: ** ** Fts3Expr.bEof (non-zero if EOF - there is no next row) ** Fts3Expr.iDocid (valid if bEof==0. The docid of the next row) ** * * If the expression is of type FTSQUERY_PHRASE, and the expression is not ** at EOF, then the following variables are populated with the position list ** for the phrase for the visited row: ** * * Fts3Expr.pPhrase->doclist.nList (length of pList in bytes) ** Fts3Expr.pPhrase->doclist.pList (pointer to position list) ** * * It says above that this function advances the expression to the next ** matching row. This is usually true, but there are the following exceptions: ** * * 1. Deferred tokens are not taken into account. If a phrase consists ** entirely of deferred tokens, it is assumed to match every row in ** the db. In this case the position-list is not populated at all. ** * * Or, if a phrase contains one or more deferred tokens and one or ** more non-deferred tokens, then the expression is advanced to the ** next possible match, considering only non-deferred tokens. In other ** words, if the phrase is "A B C", and "B" is deferred, the expression ** is advanced to the next row that contains an instance of "A * C", ** where "*" may match any single token. The position list in this case ** is populated as for "A * C" before returning. ** * * 2. NEAR is treated as AND. If the expression is "x NEAR y", it is ** advanced to point to the next row that matches "x AND y". ** * * See sqlite3Fts3EvalTestDeferred() for details on testing if a row is ** really a match, taking into account deferred tokens and NEAR operators.

***** This file contains code for the VdbeSorter object, used in concert with ** a VdbeCursor to sort large numbers of keys for CREATE INDEX statements ** or by SELECT statements with ORDER BY clauses that cannot be satisfied ** using indexes and without LIMIT clauses. ** ** The VdbeSorter object implements a multi-threaded external merge sort ** algorithm that is efficient even if the number of elements being sorted ** exceeds the available memory. ** ** Here is the (internal, non-API) interface between this module and the ** rest of the SQLite system: ** ** sqlite3VdbeSorterInit() Create a new VdbeSorter object. ** ** sqlite3VdbeSorterWrite() Add a single new row to the VdbeSorter ** object. The row is a binary blob in the ** OP_MakeRecord format that contains both ** the ORDER BY key columns and result columns ** in the case of a SELECT w/ ORDER BY, or ** the complete record for an index entry ** in the case of a CREATE INDEX. ** ** sqlite3VdbeSorterRewind() Sort all content previously added. ** Position the read cursor on the ** first sorted element. ** ** sqlite3VdbeSorterNext() Advance the read cursor to the next sorted ** element. ** ** sqlite3VdbeSorterRowkey() Return the complete binary blob for the ** row currently under the read cursor. ** ** sqlite3VdbeSorterCompare() Compare the binary blob for the row ** currently under the read cursor against ** another binary blob X and report if ** X is strictly less than the read cursor. ** Used to enforce uniqueness in a ** CREATE UNIQUE INDEX statement. ** ** sqlite3VdbeSorterClose() Close the VdbeSorter object and reclaim ** all resources. ** ** sqlite3VdbeSorterReset() Refurbish the VdbeSorter for reuse. This ** is like Close() followed by Init() only ** much faster. ** ** The interfaces above must be called in a particular order. Write() can ** only occur in between Init()/Reset() and Rewind(). Next(), Rowkey(), and ** Compare() can only occur in between Rewind() and Close()/Reset(). i.e. ** ** Init() ** for each record: Write() ** Rewind() ** Rowkey() / Compare() ** Next() ** Close() ** ** Algorithm: ** ** Records passed to the sorter via calls to Write() are initially held ** unsorted in main memory. Assuming the amount of memory used never exceeds ** a threshold, when Rewind() is called the set of records is sorted using ** an in-memory merge sort. In this case, no temporary files are required ** and subsequent calls to Rowkey(), Next() and Compare() read records ** directly from main memory. ** ** If the amount of space used to store records in main memory exceeds the ** threshold, then the set of records currently in memory are sorted and ** written to a temporary file in "Packed Memory Array" (PMA) format. ** A PMA created at this point is known as a "level-0 PMA". Higher levels ** of PMAs may be created by merging existing PMAs together - for example ** merging two or more level-0 PMAs together creates a level-1 PMA. ** ** The threshold for the amount of main memory to use before flushing ** records to a PMA is roughly the same as the limit configured for the ** page-cache of the main database. Specifically, the threshold is set to ** the value returned by "PRAGMA main.page_size" multiplied by ** that returned by "PRAGMA main.cache_size", in bytes. ** ** If the sorter is running in single-threaded mode, then all PMAs generated ** are appended to a single temporary file. Or, if the sorter is running in ** multi-threaded mode then up to (N+1) temporary files may be opened, where ** N is the configured number of worker threads. In this case, instead of ** sorting the records and writing the PMA to a temporary file itself, the ** calling thread usually launches a worker thread to do so. Except, if ** there are already N worker threads running, the main thread does the work ** itself. ** ** The sorter is running in multi-threaded mode if (a) the library was built ** with pre-processor symbol SQLITE_MAX_WORKER_THREADS set to a value greater ** than zero, and (b) worker threads have been enabled at runtime by calling ** "PRAGMA threads=N" with some value of N greater than 0. ** ** When Rewind() is called, any data remaining in memory is flushed to a ** final PMA. So at this point the data is stored in some number of sorted ** PMAs within temporary files on disk. ** ** If there are fewer than SORTER_MAX_MERGE_COUNT PMAs in total and the ** sorter is running in single-threaded mode, then these PMAs are merged ** incrementally as keys are retrieved from the sorter by the VDBE. The ** MergeEngine object, described in further detail below, performs this ** merge. ** ** Or, if running in multi-threaded mode, then a background thread is ** launched to merge the existing PMAs. Once the background thread has ** merged T bytes of data into a single sorted PMA, the main thread ** begins reading keys from that PMA while the background thread proceeds ** with merging the next T bytes of data. And so on. ** ** Parameter T is set to half the value of the memory threshold used ** by Write() above to determine when to create a new PMA. ** ** If there are more than SORTER_MAX_MERGE_COUNT PMAs in total when ** Rewind() is called, then a hierarchy of incremental-merges is used. ** First, T bytes of data from the first SORTER_MAX_MERGE_COUNT PMAs on ** disk are merged together. Then T bytes of data from the second set, and ** so on, such that no operation ever merges more than SORTER_MAX_MERGE_COUNT ** PMAs at a time. This done is to improve locality. ** ** If running in multi-threaded mode and there are more than ** SORTER_MAX_MERGE_COUNT PMAs on disk when Rewind() is called, then more ** than one background thread may be created. Specifically, there may be ** one background thread for each temporary file on disk, and one background ** thread to merge the output of each of the others to a single PMA for ** the main thread to read from.

label: code-design

76531. Length of BTM vector

76532. RELEASE

76533. ** The following version of unixSectorSize() is optimized for QNX.

76534. Opcode: Savepoint P1 * * P4 * * ** Open, release or rollback the savepoint named by parameter P4, depending ** on the value of P1. To open a new savepoint, P1==0. To release (commit) an ** existing savepoint, P1==1, or to rollback an existing savepoint P1==2.

76535. res might be negative because the table is empty. Check to ** see if this is the case.

76536. A DELETE operation. Foreign key processing is required if the ** table in question is either the child or parent table for any ** foreign key constraint.

76537. ** Shorthand for the functions above

76538. Replacement content for JNODE_REPLACE

76539. ** Close the read-only blob handle, if it is open.

76540. ** Page paths: ** ** The value of the 'path' column describes the path taken from the ** root-node of the b-tree structure to each page. The value of the ** root-node path is '/'. ** ** The value of the path for the left-most child page of the root of ** a b-tree is '000/'. (Btrees store content ordered from left to right ** so the pages to the left have smaller keys than the pages to the right.) ** The next to left-most child of the root page is ** '001', and so on, each sibling page identified by a 3-digit hex ** value. The children of the 451st left-most sibling have paths such ** as '/1c2/000/, '/1c2/001' etc. ** ** Overflow pages are specified by appending a '+' character and a ** six-digit hexadecimal value to the path to the cell they are linked ** from. For example, the three overflow pages in a chain linked from ** the left-most cell of the 450th child of the root page are identified ** by the paths: ** ** '/1c2/000+000000' // First page in overflow chain ** '/1c2/000+000001' // Second page in overflow chain ** '/1c2/000+000002' // Third page in overflow chain ** ** If the paths are sorted using the BINARY collation sequence, then ** the overflow pages associated with a cell will appear earlier in the ** sort-order than its child page: ** ** '/1c2/000' // Left-most child of 451st child of root

76572. Database schema version number for this file
76573. ** Return the number of changes since the database handle was opened.
76574. ** If the WHERE_GROUPBY flag is set in the mask passed to sqlite3WhereBegin(), ** the planner assumes that the specified pOrderBy list is actually a GROUP BY clause - and so any order that groups rows as required satisfies the ** request. ** ** Normally, in this case it is not possible for the caller to determine ** whether or not the rows are really being delivered in sorted order, or ** just in some other order that provides the required grouping. However, ** if the WHERE_SORTBYGROUP flag is also passed to sqlite3WhereBegin(), then ** this function may be called on the returned WhereInfo object. It returns ** true if the rows really will be sorted in the specified order, or false ** otherwise. ** ** For example, assuming: ** ** CREATE INDEX i1 ON t1(x, Y); ** ** then ** ** SELECT * FROM t1 GROUP BY x,y ORDER BY x,y; -- IsSorted() == 1 ** SELECT * FROM t1 GROUP BY y,x ORDER BY y,x; -- IsSorted() == 0
76575. **comment:** Following an incremental-merge operation, assuming that the input ** segments are not completely consumed (the usual case), they are updated ** in place to remove the entries that have already been merged. This ** involves updating the leaf block that contains the smallest unmerged ** entry and each block (if any) between the leaf and the root node. So ** if the height of the input segment b-trees is N, and input segments ** are merged eight at a time, updating the input segments at the end ** of an incremental-merge requires writing (8*(1+N)) blocks. N is usually ** small - often between 0 and 2. So the overhead of the incremental ** merge is somewhere between 8 and 24 blocks. To avoid this overhead ** dwarfing the actual productive work accomplished, the incremental merge ** is only attempted if it will write at least 64 leaf blocks. Hence ** nMinMerge. ** ** Of course, updating the input segments also involves deleting a bunch ** of blocks from the segments table. But this is not considered overhead ** as it would also be required by a crisis-merge that used the same input ** segments.

76715. Form the KeyInfo object from this ExprList
76716. a pointer to a SrcList
76717. **comment:** The following value requires a mutex to change. We skip the mutex on ** reading because (1) most platforms read a 32-bit integer atomically and ** (2) even if an incorrect value is read, no great harm is done since this ** is really just an optimization.
 label: code-design
76718. Free the contents of the apShm[] array. And the array itself.
76719. This is a utility routine used to set the ExprSpan.zStart and ** ExprSpan.zEnd values of pOut so that the span covers the complete ** range of text beginning with pStart and going to the end of pEnd.
76720. ** Deallocate a WhereClause structure. The WhereClause structure ** itself is not freed. This routine is the inverse of ** sqlite3WhereClauseInit().
76721. Opcode: IfPos P1 P2 P3 * * * Synopsis: if r[P1]>0 then r[P1]=P3, goto P2 ** ** Register P1 must contain an integer. ** If the value of register P1 is 1 or greater, subtract P3 from the ** value in P1 and jump to P2. ** ** If the initial value of register P1 is less than 1, then the ** value is unchanged and control passes through to the next instruction.
76722. Target table for DELETE, UPDATE, INSERT
76723. **comment:** 0x8000 not currently used
 label: code-design
76724. 0x01. Next integer will be a column number.
76725. 30..37 01234567
76726. OUT: pointer to doclist
76727. To assert pCache->nPage is correct
76728. Result of sqlite3_reset()
76729. OFFSET value. NULL means no offset
76730. Number of slots allocated for aPoint[]
76731. ** Query status information.

76732. ** Return TRUE if the mask of type in eType matches no bits of the type of the ** allocation p. Also return true if p==NULL. *** This routine is designed for use within an assert() statement, to ** verify the type of an allocation. For example: *** assert(sqlite3MemdebugNoType(p, MEMTYPE_LOOKASIDE));

76733. ** An instance of this structure is used to manage a pair of buffers, each ** (nElem * sizeof(u32)) bytes in size. See the MatchinfoBuffer code below ** for details.

76734. **comment:** Calculate a hash value for this term. This is the same hash checksum ** used by the fts5_hash.c module. This is not important for correct ** operation of the module, but is necessary to ensure that some tests ** designed to produce hash table collisions really do work.

label: code-design

76735. ** Reset the tokenizer cursor passed as the only argument. As if it had ** just been returned by fts3tokOpenMethod().

76736. Length of zMod in bytes

76737. IMP: R-25361-16150 This function is omitted from SQLite by default. It ** is only available if the SQLITE_SOUNDEX compile-time option is used ** when SQLite is built.

76738. 0x8

76739. database name - used by the update hook

76740. Content of the new cell

76741. Unused file descriptors to close

76742. **comment:** Make sure the new table name does not collide with an existing ** index or table name in the same database. Issue an error message if ** it does. The exception is if the statement being parsed was passed ** to an sqlite3_declare_vtab() call. In that case only the column names ** and types will be used, so there is no need to test for namespace ** collisions.

label: code-design

76743. ** Each open file is managed by a separate instance of the "Pager" structure.

76744. Array of collation sequence names for index

76745. NEED_SYNC can be set independently of WRITEABLE. This can happen, ** for example, when using the sqlite3PagerDontWrite() optimization: ** (1) Page X is journalled, and gets WRITEABLE and NEED_SEEK. ** (2) Page X moved to freelist, WRITEABLE is cleared ** (3) Page X reused, WRITEABLE is set again ** If NEED_SYNC had been cleared in step 2, then it would not be reset ** in step 3, and page might be written into the database without first ** syncing the rollback journal, which might cause corruption on a power ** loss. *** Another example is when the database page size is smaller than the ** disk sector size. When any page of a sector is journalled, all pages ** in that sector are marked NEED_SYNC even if they are still CLEAN, just ** in case they are later modified, since all pages in the same sector ** must be journalled and synced before any of those pages can be safely ** written.

76746. type of the previous token

76747. **comment:** Initialize the malloc() system and the recursive pInitMutex mutex. ** This operation is protected by the STATIC_MASTER mutex. Note that ** MutexAlloc() is called for a static mutex prior to initializing the ** malloc subsystem - this implies that the allocation of a static ** mutex must not require support from the malloc subsystem.

label: code-design

76748. The precision in %q and %Q means how many input characters to ** consume, not the length of the output... ** if(precision>=0 && precision<length) length = precision;

76749. ** cnt==0 means there was not match. cnt>1 means there were two or ** more matches. Either way, we have an error.

76750. The TK_SELECT_COLUMN Expr node: *** pLeft: pVector containing TK_SELECT. Not deleted. ** pRight: not used. But recursively deleted. ** iColumn: Index of a column in pVector ** iTable: 0 or the number of columns on the LHS of an assignment ** pLeft->iTable: First in an array of register holding result, or 0 ** if the result is not yet computed. *** sqlite3ExprDelete() specifically skips the recursive delete of ** pLeft on TK_SELECT_COLUMN nodes. But pRight is followed, so pVector ** can be attached to pRight to cause this node to take ownership of ** pVector. Typically there will be multiple TK_SELECT_COLUMN nodes ** with the same pLeft pointer to the pVector, but only one of them ** will own the pVector.

76751. Jump here (skipping the main loop body subroutine) if the ** current sub-WHERE row is a duplicate from prior sub-WHERES.

76752. COMMIT => nothing

76753. Has no LIMIT clause

76754. WRITEABLE pages must also be DIRTY

76755. Number of bits handled by each apSub[] entry.

76756. Release the reference to the new page.

76757. When reducing a lock such that other processes can start ** reading the database file again, make sure that the ** transaction counter was updated if any part of the database ** file changed. If the transaction counter is not updated, ** other connections to the same file might not realize that ** the file has changed and hence might not know to flush their ** cache. The use of a stale cache can lead to database corruption.

76758. Object completely outside of query region

76759. VDBE under construction

76760. Largest permissible value of i

76761. ** The following singleton contains the global configuration for ** the SQLite library.

76762. The last rowid in the doclist may not be on the current page. Search ** forward to find the page containing the last rowid.

76763. Size of every page in this cache

76764. ** Return the size of the prefix, in bytes, that buffer ** (pNew/<length-unknown>) shares with buffer (pOld/nOld). *** Buffer (pNew/<length-unknown>) is guaranteed to be greater ** than buffer (pOld/nOld).

76765. Offset of header in journal file

76766. 6: (start_constraints && startEq && !bRev)

76767. Opcode: Rewind P1 P2 * * * * * The next use of the Rowid or Column or Next instruction for P1 ** will refer to the first entry in the database table or index. ** If the table or index is empty, jump immediately to P2. ** If the table or index is not empty, fall through to the following ** instruction. *** This opcode leaves the cursor configured to move in forward order, ** from the beginning toward the end. In other words, the cursor is ** configured to use Next, not Prev.

76768. ** This vector defines all the methods that can operate on an ** sqlite3_file for win32.

76769. Write the current in-memory list to a PMA. When the VdbeSorterWrite() ** function flushes the contents of memory to disk, it immediately always ** creates a new list consisting of a single key immediately afterwards. ** So the list is never empty at this point.

76770. Value of %_segdir.start_block

76771. ** Release all the table locks (locks obtained via calls to ** the setSharedCacheTableLock() procedure) held by Btree object p. *** This function assumes that Btree p has an open read or write ** transaction. If it does not, then the BTS_PENDING flag ** may be incorrectly cleared.

76772. ** Structure allocated for each backup operation.

76773. **comment:** The pager this page is part of

label: documentation

76774. isOrdered for (pFrom+pWLoop)

76775. Condition 1

76776. ** Resolve an expression that was part of an ATTACH or DETACH statement. This ** is slightly different from resolving a normal SQL expression, because simple ** identifiers are treated as strings, not possible column names or aliases. *** i.e. if the parser sees: *** ATTACH DATABASE abc AS def *** it treats the two expressions as literal strings 'abc' and 'def' instead of ** looking for columns of the same name. *** This only applies to the root node of pExpr, so the statement: *** ATTACH DATABASE abc||def AS 'db2' *** will fail because neither abc or def can be resolved.

76777. Calculate the length in bytes and the checksum of zMaster

76778. 323

76779. Cell extends past end of page

76780. Each element in the hash table is an instance of the following ** structure. All elements are stored on a single doubly-linked list. *** Again, this structure is intended to be opaque, but it can't really ** be opaque because it is used by macros.

76781. True if pParent is a root-page

76782. **comment:** Balance the tree. If the entry deleted was located on a leaf page, ** then the cursor still points to that page. In this case the first ** call to balance() repairs the tree, and the if(...) condition is ** never true. *** Otherwise, if the entry deleted was on an internal node page, then ** pCur is pointing to the leaf page from which a cell was removed to ** replace the cell deleted from the internal node. This is slightly ** tricky as the leaf node may be underfull, and the internal node may ** be either under or overfull. In this case run the balancing algorithm ** on the leaf node first. If the balance proceeds far enough up the ** tree that we can be sure that any problem in the internal node has ** been corrected, so be it. Otherwise, after balancing the leaf node, ** walk the cursor up the tree to the internal node and balance it as ** well.

label: code-design

76783. ** A cursor is a pointer to a particular entry within a particular b-tree within a database file. *** The entry is identified by its MemPage and the index in ** MemPage.aCell[] of the entry. *** A single database file can be shared by two more database connections, ** but cursors cannot be shared. Each cursor is associated with a ** particular database connection identified BtCursor.pBtree.db. *** Fields in this structure are accessed under the BtShared.mutex ** found at self->pBt->mutex. *** skipNext meaning: ** eState==SKIPNEXT && skipNext>0: Next sqlite3BtreeNext() is no-op. ** eState==SKIPNEXT && skipNext<0: Next sqlite3BtreePrevious() is no-op. ** eState==FAULT: Cursor fault with skipNext as error code.
76784. Use the standard library for separate compilation
76785. Search for a deferred foreign key constraint for which this table ** is the child table. If one cannot be found, return without ** generating any VDBE code. If one can be found, then jump over ** the entire DELETE if there are no outstanding deferred constraints ** when this statement is run.
76786. Next value in position list
76787. Rollback any active transaction and free the handle structure. ** The call to sqlite3BtreeRollback() drops any table-locks held by ** this handle.
76788. ***** Begin file fts5.c *****
76789. If the p5 flag is clear, then recursive invocation of triggers is ** disabled for backwards compatibility (p5 is set if this sub-program ** is really a trigger, not a foreign key action, and the flag set ** and cleared by the "PRAGMA recursive_triggers" command is clear). *** It is recursive invocation of triggers, at the SQL level, that is ** disabled. In some cases a single trigger may generate more than one ** SubProgram (if the trigger may be executed with more than one different ** ON CONFLICT algorithm). SubProgram structures associated with a ** single trigger all have the same value for the SubProgram.token ** variable.

76840. with ::= WITH wqlist

76841. ** Return the sum of the reference counts for all pages held by pPager.

76842. Overflow chain ends prematurely

76843. Maybe another cursor on the same btree

76844. Number of bytes to lock

76845. ** Walk an expression tree. Return non-zero if the expression is constant ** or a function call with constant arguments. Return and 0 if there ** are any variables. ** ** For the purposes of this function, a double-quoted string (ex: "abc") ** is considered a variable but a single-quoted string (ex: 'abc') is ** a constant.

76846. ** Search for a term in the WHERE clause that is of the form "X <op> <expr>" ** where X is a reference to the iColumn of table iCur or of index pIdx ** if pIdx!=0 and <op> is one of the WO_xx operator codes specified by ** the op parameter. Return a pointer to the term. Return 0 if not found. ** ** If pIdx!=0 then it must be one of the indexes of table iCur. ** Search for terms matching the iColumn-th column of pIdx ** rather than the iColumn-th column of table iCur. ** ** The term returned might be Y=<expr> if there is another constraint in ** the WHERE clause that specifies that X=Y. Any such constraints will be ** identified by the WO_EQUIV bit in the pTerm->eOperator field. The ** aiCur[]/aiColumn[] arrays hold X and all its equivalents. There are 11 ** slots in aiCur[]/aiColumn[] so that means we can look for X plus up to 10 ** other equivalent values. Hence a search for X will return <expr> if X=A1 ** and A1=A2 and A2=A3 and ... and A9=A10 and A10=<expr>. ** ** If there are multiple terms in the WHERE clause of the form "X <op> <expr>" ** then try for the one with no dependencies on <expr> - in other words where ** <expr> is a constant expression of some kind. Only return entries of ** the form "X <op> Y" where Y is a column in another table if no terms of ** the form "X <op> <const-exp>" exist. If no terms with a constant RHS ** exist, try to return a term that does not use WO_EQUIV.

76847. ** Return the bitwise-OR of all Expr.flags fields in the given ** ExprList.

76848. Destination page size

76849. Number of bytes in buffer aRecord[]

76850. ** Move the open database page pDbPage to location iFreePage in the ** database. The pDbPage reference remains valid. ** ** The isCommit flag indicates that there is no need to remember that ** the journal needs to be sync()ed before database page pDbPage->pgno ** can be written to. The caller has already promised not to write to that ** page.

76851. ** This function is a no-op unless currently processing an EXPLAIN QUERY PLAN ** command, or if either SQLITE_DEBUG or SQLITE_ENABLE_STMT_SCANSTATUS was ** defined at compile-time. If it is not a no-op, a single OP_Explain opcode ** is added to the output to describe the table scan strategy in pLevel. ** ** If an OP_Explain opcode is added to the VM, its address is returned. ** Otherwise, if no OP_Explain is coded, zero is returned.

76852. Total number of calls to malloc

76853. ** Same as above, except that this implementation works for WinRT.

76854. Index in mem3.aPool[] of previous free chunk

77284. star_opt ::=

77285. Finally, delete what is left of the subquery and return ** success.

77286. Generate the subroutine return

77287. Mask of cursor flags (see below)

77288. we couldn't create the proxy lock file with the old lock file path ** so try again via auto-naming

77289. Appending to an existing hash-entry. Check that there is enough ** space to append the largest possible new entry. Worst case scenario ** is: *** + 9 bytes for a new rowid, ** + 4 byte reserved for the "poslist size" varint. ** + 1 byte for a "new column" byte, ** + 3 bytes for a new column number (16-bit max) as a varint, ** + 5 bytes for the new position offset (32-bit max).

77290. The ORDER BY and GROUP BY clauses may not refer to terms in ** outer queries

77291. leaves_end_block

77292. Do the rest of the initialization under the recursive mutex so ** that we will be able to handle recursive calls into ** sqlite3_initialize(). The recursive calls normally come through ** sqlite3_os_init() when it invokes sqlite3_vfs_register(), but other ** recursive calls might also be possible. *** IMPLEMENTATION-OF: R-00140-37445 SQLite automatically serializes calls ** to the xInit method, so the xInit method need not be threadsafe. *** The following mutex is what serializes access to the appdef pcache xInit ** methods. The sqlite3_pcachemethods.xInit() all is embedded in the ** call to sqlite3PcacheInitialize().

77293. Load an unaligned and unsigned 32-bit integer

77294. ** Compare the contents of the pLeft buffer with the pRight/nRight blob. ** ** Return -ve if pLeft is smaller than pRight, 0 if they are equal or ** +ve if pRight is smaller than pLeft. In other words: *** res = *pLeft - *pRight

77295. ***** Everything after this point is just test code.

77296. OUT: uid of zFile.

77297. Not the root node

77298. Bitmap of additional columns

77299. Obtain the average docsize (in pages).

77300. ** The various operations on open token or token prefix iterators opened ** using sqlite3Fts5IndexQuery().

77301. ** pZ is a UTF-8 encoded unicode string. If nByte is less than zero, ** return the number of unicode characters in pZ up to (but not including) ** the first 0x00 byte. If nByte is not less than zero, return the ** number of unicode characters in the first nByte of pZ (or up to ** the first 0x00, whichever comes first).

77302. The first nOBSat columns of the previous row

77303. Opcode: AggFinal P1 P2 * P4 *** Synopsis: accum=r[P1] N=P2 *** Execute the finalizer function for an aggregate. P1 is ** the memory location that is the accumulator for the aggregate. *** P2 is the number of arguments that the step function takes and ** P4 is a pointer to the FuncDef for this function. The P2 ** argument is not used by this opcode. It is only there to disambiguate ** functions that can take varying numbers of arguments. The ** P4 argument is only needed for the degenerate case where ** the step function was not previously called.

77304. 1170

77305. ** Subterms pOne and pTwo are contained within WHERE clause pWC. The ** two subterms are in disjunction - they are OR-ed together. *** If these two terms are both of the form: "A op B" with the same ** A and B values but different operators and if the operators are ** compatible (if one is = and the other is <, for example) then ** add a new virtual AND term to pWC that is the combination of the ** two. *** Some examples: *** x<y OR x=y --> x<=y ** x=y OR x=y --> x<=y ** x<=y OR x<y --> x<=y *** The following is NOT generated: *** x<y OR x>y --> x!=y

77306. Containing WITH clause, or NULL

77307. End if not an rowid index

77308. ** Playback savepoint pSavepoint. Or, if pSavepoint==NULL, then playback ** the entire master journal file. The case pSavepoint==NULL occurs when ** a ROLLBACK TO command is invoked on a SAVEPOINT that is a transaction ** savepoint. *** When pSavepoint is not NULL (meaning a non-transaction savepoint is ** being rolled back), then the rollback consists of up to three stages, ** performed in the order specified: *** * Pages are played back from the main journal starting at byte ** offset PagerSavepoint.iOffset and continuing to ** PagerSavepoint.iHdrOffset, or to the end of the main journal ** file if PagerSavepoint.iHdrOffset is zero. *** * If PagerSavepoint.iHdrOffset is not zero, then pages are played ** back starting from the journal header immediately following ** PagerSavepoint.iHdrOffset to the end of the main journal file. *** * Pages are then played back from the sub-journal file, starting ** with the PagerSavepoint.iSubRec and continuing to the end of ** the journal file. *** Throughout the rollback process, each time a page is rolled back, the ** corresponding bit is set in a bitvec structure (variable pDone in the ** implementation below). This is used to ensure that a page is only ** rolled back the first time it is encountered in either journal. *** If pSavepoint is NULL, then pages are only played back from the main ** journal file. There is no need for a bitvec in this case. *** In either case, before playback commences the Pager.dbSize variable ** is reset to the value that it held at the start of the savepoint ** (or transaction). No page with a page-number greater than this value ** is played back. If one is encountered it is simply skipped.

77309. ** Find the current time (in Universal Coordinated Time). Write into *piNow ** the current time and date as a Julian Day number times 86_400_000. In ** other words, write into *piNow the number of milliseconds since the Julian ** epoch of noon in Greenwich on November 24, 4714 B.C according to the ** proleptic Gregorian calendar. *** On success, return SQLITE_OK. Return SQLITE_ERROR if the time and date ** cannot be found.

77310. ** The winFile structure is a subclass of sqlite3_file* specific to the win32 ** portability layer.

77311. 289

77312. True if this is a VIEW

77313. destructor for json_each virtual table

77314. Add a WO_MATCH auxiliary term to the constraint set if the ** current expression is of the form: column MATCH expr. ** This information is used by the xBestIndex methods of ** virtual tables. The native query optimizer does not attempt ** to do anything with MATCH functions.

77315. IN/OUT: Pointer to position list

77316. ** The pVal argument is known to be a value other than NULL. ** Convert it into a string with encoding enc and return a pointer ** to a zero-terminated version of that string.

77317. **comment:** Malloc utility

77352. **comment:** ** This routine redistributes cells on the iParentIdx'th child of pParent ** (hereafter "the page") and up to 2 siblings so that all pages have about the ** same amount of free space. Usually a single sibling on either side of the ** page are used in the balancing, though both siblings might come from one ** side if the page is the first or last child of its parent. If the page ** has fewer than 2 siblings (something which can only happen if the page ** is a root page or a child of a root page) then all available siblings ** participate in the balancing. ** ** The number of siblings of the page might be increased or decreased by ** one or two in an effort to keep pages nearly full but not over full. ** ** Note that when this routine is called, some of the cells on the page ** might not actually be stored in MemPage.aData[]. This can happen ** if the page is overfull. This routine ensures that all cells allocated ** to the page and its siblings fit into MemPage.aData[] before returning. ** ** In the course of balancing the page and its siblings, cells may be ** inserted into or removed from the parent page (pParent). Doing so ** may cause the parent page to become overfull or underfull. If this ** happens, it is the responsibility of the caller to invoke the correct ** balancing routine to fix this problem (see the balance() routine). ** ** If this routine fails for any reason, it might leave the database ** in a corrupted state. So if this routine fails, the database should ** be rolled back. ** ** The third argument to this function, aOvflSpace, is a pointer to a ** buffer big enough to hold one page. If while inserting cells into the parent ** page (pParent) the parent page becomes overfull, this buffer is ** used to store the parent's overflow cells. Because this function inserts ** a maximum of four divider cells into the parent page, and the maximum ** size of a cell stored within an internal node is always less than 1/4 ** of the page-size, the aOvflSpace[] buffer is guaranteed to be large ** enough for all overflow cells. ** ** If aOvflSpace is set to a null pointer, this function returns **
SQLITE_NOMEM.

Or, if iCol is ** non-negative but less than the number of columns in the table, return ** the total number of tokens in column iCol, considering all rows in ** the FTS5 table. *** ** If parameter iCol is greater than or equal to the number of columns ** in the table, SQLITE_RANGE is returned. Or, if an error occurs (e.g. ** an OOM condition or IO error), an appropriate SQLite error code is ** returned. *** ** xColumnCount(pFts): ** Return the number of columns in the table. *** ** xColumnSize(pFts, iCol, pnToken): ** If parameter iCol is less than zero, set output variable *pnToken ** to the total number of tokens in the current row. Or, if iCol is ** non-negative but less than the number of columns in the table, set ** *pnToken to the number of tokens in column iCol of the current row. *** ** If parameter iCol is greater than or equal to the number of columns ** in the table, SQLITE_RANGE is returned. Or, if an error occurs (e.g. ** an OOM condition or IO error), an appropriate SQLite error code is ** returned. *** ** This function may be quite inefficient if used with an FTS5 table ** created with the "columnsize=0" option. *** ** xColumnText: ** This function attempts to retrieve the text of column iCol of the ** current document. If successful, (*pz) is set to point to a buffer ** containing the text in utf-8 encoding, (*pn) is set to the size in bytes ** (not characters) of the buffer and SQLITE_OK is returned. Otherwise, ** if an error occurs, an SQLite error code is returned and the final values ** of (*pz) and (*pn) are undefined. *** ** xPhraseCount: ** Returns the number of phrases in the current query expression. *** ** xPhraseSize: ** Returns the number of tokens in phrase iPhrase of the query. Phrases ** are numbered starting from zero. *** ** xInstCount: ** Set *pnInst to the total number of occurrences of all phrases within ** the query within the current row. Return SQLITE_OK if successful, or ** an error code (i.e. SQLITE_NOMEM) if an error occurs. *** ** This API can be quite slow if used with an FTS5 table created with the ** "detail=none" or "detail=column" option. If the FTS5 table is created ** with either "detail=none" or "detail=column" and "content=" option ** (i.e. if it is a contentless table), then this API always returns 0. *** ** xInst: ** Query for the details of phrase match iIdx within the current row. ** Phrase matches are numbered starting from zero, so the iIdx argument ** should be greater than or equal to zero and smaller than the value ** output by xInstCount(). *** ** Usually, output parameter *piPhrase is set to the phrase number, *piCol ** to the column in which it occurs and *piOff the token offset of the ** first token of the phrase. The exception is if the table was created ** with the offsets=0 option specified. In this case *piOff is always ** set to -1. *** ** Returns SQLITE_OK if successful, or an error code (i.e. SQLITE_NOMEM) ** if an error occurs. *** ** This API can be quite slow if used with an FTS5 table created with the ** "detail=none" or "detail=column" option. *** ** xRowid: ** Returns the rowid of the current row. *** ** xTokenize: ** Tokenize text using the tokenizer belonging to the FTS5 table. *** ** xQueryPhrase(pFts5, iPhrase, pUserData, xCallback): ** This API function is used to query the FTS table for phrase iPhrase ** of the current query. Specifically, a query equivalent to: *** ... FROM ftstable WHERE ftstable MATCH \$p ORDER BY rowid *** with \$p set to a phrase equivalent to the phrase iPhrase of the ** current query is executed. Any column filter that applies to ** phrase iPhrase of the current query is included in \$p. For each ** row visited, the callback function passed as the fourth argument ** is invoked. The context and API objects passed to the callback ** function may be used to access the properties of each matched row. ** Invoking Api.xUserData() returns a copy of the pointer passed as ** the third argument to pUserData. *** ** If the callback function returns any value other than SQLITE_OK, the ** query is abandoned and the xQueryPhrase function returns immediately. ** If the returned value is SQLITE_DONE, xQueryPhrase returns SQLITE_OK. ** Otherwise, the error code is propagated upwards. ** ** If the query runs to completion without incident, SQLITE_OK is returned. ** Or, if some error occurs before the query completes or is aborted by ** the callback, an SQLite error code is returned. *** ** xSetAuxdata(pFts5, pAux, xDelete) ** ** Save the pointer passed as the second argument as the extension functions ** "auxiliary data". The pointer may then be retrieved by the current or any ** future invocation of the same fts5 extension function made as part of ** of the same MATCH query using the xGetAuxdata() API. *** ** Each extension function is allocated a single auxiliary data slot for ** each FTS query (MATCH expression). If the extension function is invoked ** more than once for a single FTS query, then all invocations share a ** single auxiliary data context. *** ** If there is already an auxiliary data pointer when this function is ** invoked, then it is replaced by the new pointer. If an xDelete callback ** was specified along with the original pointer, it is invoked at this ** point. *** ** The xDelete callback, if one is specified, is also invoked on the ** auxiliary data pointer after the FTS5 query has finished. *** ** If an error (e.g. an OOM condition) occurs within this function, an ** the auxiliary data is set to NULL and an error code returned. If the ** xDelete parameter was not NULL, it is invoked on the auxiliary data ** pointer before returning. *** ** xGetAuxdata(pFts5, bClear) ** ** Returns the current auxiliary data pointer for the fts5 extension ** function. See the xSetAuxdata() method for details. *** ** If the bClear argument is non-zero, then the auxiliary data is cleared ** (set to NULL) before this function returns. In this case the xDelete, ** if any, is not invoked. *** ** xRowCount(pFts5, pnRow) ** ** This function is used to retrieve the total number of rows in the table. ** In other words, the same value that would be returned by: ** SELECT count(*) FROM ftstable; *** ** xPhraseFirst(): ** This function is used, along with type Fts5PhraseIter and the xPhraseNext() method, to iterate through all instances of a single query phrase within ** the current row. This is the same information as is accessible via the ** xInstCount/xInst APIs. While the xInstCount/xInst APIs are more convenient ** to use, this API may be faster under some circumstances. To iterate ** through instances of phrase iPhrase, use the following code: *** ** Fts5PhraseIter iter; ** int iCol, iOff; ** for(pApi->xPhraseFirst(pFts, iPhrase, &iter, &iCol, &iOff); ** iCol>=0; ** pApi->xPhraseNext(pFts, &iter, &iCol, &iOff) **){ ** // An instance of phrase iPhrase at offset iOff of column iCol ** } *** ** The Fts5PhraseIter structure is defined above. Applications should not ** modify this structure directly - it should only be used as shown above ** with the xPhraseFirst() and xPhraseNext() API methods (and by ** xPhraseFirstColumn() and xPhraseNextColumn() as illustrated below). *** ** This API can be quite slow if used with an FTS5 table created with the ** "detail=none" or "detail=column" option. If the FTS5 table is created ** with either "detail=none" or "detail=column" and "content=" option ** (i.e. if it is a contentless table), then this API always iterates ** through an empty set (all calls to xPhraseFirst() set iCol to -1). *** ** xPhraseNext(): ** See xPhraseFirst above. *** ** xPhraseFirstColumn(): ** This function and xPhraseNextColumn() are similar to the xPhraseFirst() ** and xPhraseNext() APIs described above. The difference is that instead ** of iterating through all instances of a phrase in the current row, these ** APIs are used to iterate through the set of columns in the current row ** that contain one or more instances of a specified phrase. For example: *** ** Fts5PhraseIter iter; ** int iCol; ** for(pApi->xPhraseFirstColumn(pFts, iPhrase, &iter, &iCol); ** iCol>=0; ** pApi->xPhraseNextColumn(pFts, &iter, &iCol) **){ ** // Column iCol contains at least one instance of phrase iPhrase ** } *** ** This API can be quite slow if used with an FTS5 table created with the ** "detail=none" option. If the FTS5 table is created with either ** "detail=none" or "content=" option (i.e. if it is a contentless table), ** then this API always iterates through an empty set (all calls to ** xPhraseFirstColumn() set iCol to -1). *** ** The information accessed using this API and its companion ** xPhraseFirstColumn() may also be obtained using xPhraseFirst/xPhraseNext ** (or xInst/xInstCount). The chief advantage of this API is that it is ** significantly more efficient than those alternatives when used with ** "detail=column" tables. *** ** xPhraseNextColumn(): ** See xPhraseFirstColumn above.

Another ** big comment (similar to this one) will mark the point in the code where ** we transition back to normal indentation. ** ** The formatting of each case is important. The makefile for SQLite ** generates two C files "opcodes.h" and "opcodes.c" by scanning this ** file looking for lines that begin with "case OP_". The opcodes.h files ** will be filled with #defines that give unique integer values to each ** opcode and the opcodes.c file is filled with an array of strings where ** each string is the symbolic name for the corresponding opcode. If the ** case statement is followed by a comment of the form "# same as ... #" ** that comment is used to determine the particular value of the opcode. ** ** Other keywords in the comment that follows each case are used to ** construct the OPFLG_INITIALIZER value that initializes opcodeProperty[J]. ** Keywords include: in1, in2, in3, out2, out3. See ** the mkopcodeh.awk script for additional information. ** ** Documentation about VDBE opcodes is generated by scanning this file ** for lines of that contain "Opcode:". That line and all subsequent ** comment lines are used in the generation of the opcode.html documentation ** file. ** ** SUMMARY: ** ** Formatting is important to scripts that scan this file. ** Do not deviate from the formatting style currently in use. *****
77422. Number used to identify the index
77423. Initialize the name-context
77424. Begin writing at this offset into the file
77425. cmd ::= PRAGMA nm dbnm
77426. **comment:** If the payload will not fit completely on the local page, we have ** to decide how much to store locally and how much to spill onto ** overflow pages. The strategy is to minimize the amount of unused ** space on overflow pages while keeping the amount of local storage ** in between minLocal and maxLocal. ** ** Warning: changing the way overflow payload is distributed in any ** way will result in an incompatible file format.

77563. Wildcard of the form "?nnn". Convert "nnn" to an integer and ** use it as the variable number
77564. ** An instance of the following structure is used by the tree walker ** to count references to table columns in the arguments of an ** aggregate function, in order to implement the ** sqlite3FunctionThisSrc() routine.
77565. EVIDENCE-OF: R-49794-35026 Value is a big-endian 16-bit ** twos-complement integer.
77566. **comment:** ** Attempt to start a read transaction. This might fail due to a race or ** other transient condition. When that happens, it returns WAL_RETRY to ** indicate to the caller that it is safe to retry immediately. *** On success return SQLITE_OK. On a permanent failure (such an ** I/O error or an SQLITE_BUSY because another process is running ** recovery) return a positive error code. *** The useWal parameter is true to force the use of the WAL and disable ** the case where the WAL is bypassed because it has been completely ** checkpointed. If useWal==0 then this routine calls walIndexReadHdr() ** to make a copy of the wal-index header into pWal->hdr. If the ** wal-index header has changed, *pChanged is set to 1 (as an indication ** to the caller that the local paget cache is obsolete and needs to be ** flushed.) When useWal==1, the wal-index header is assumed to already ** be loaded and the pChanged parameter is unused. ***
 The caller must set the cnt parameter to the number of prior calls to ** this routine during the current read attempt that returned WAL_RETRY. ** This routine will

start taking more aggressive measures to clear the ** race conditions after multiple WAL_RETRY returns, and after an excessive ** number of errors will ultimately return SQLITE_PROTOCOL. The ** SQLITE_PROTOCOL return indicates that some other process has gone rogue ** and is not honoring the locking protocol. There is a vanishingly small ** chance that SQLITE_PROTOCOL could be returned because of a run of really ** bad luck when there is lots of contention for the wal-index, but that ** possibility is so small that it can be safely neglected, we believe. *** On success, this routine obtains a read lock on ** WAL_READ_LOCK(pWal->readLock). The pWal->readLock integer is ** in the range $0 \leq pWal->readLock < WAL_NREADER$. If pWal->readLock==(-1) ** that means the Wal does not hold any read lock. The reader must not ** access any database page that is modified by a WAL frame up to and ** including frame number aReadMark[pWal->readLock]. The reader will ** use WAL frames up to and including pWal->hdr.mxFrame if pWal->readLock>0 ** Or if pWal->readLock==0, then the reader will ignore the WAL ** completely and get all content directly from the database file. ** If the useWal parameter is 1 then the WAL will never be ignored and ** this routine will always set pWal->readLock>0 on success. ** When the read transaction is completed, the caller must release the ** lock on WAL_READ_LOCK(pWal->readLock) and set pWal->readLock to -1. *** This routine uses the nBackfill and aReadMark[] fields of the header ** to select a particular WAL_READ_LOCK() that strives to let the ** checkpoint process do as much work as possible. This routine might ** update values of the aReadMark[] array in the header, but if it does ** so it takes care to hold an exclusive lock on the corresponding ** WAL_READ_LOCK() while changing values.

77599. ** 2010 August 30 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **

77600. ** Delete all information from a single table in the database. iTTable is ** the page number of the root of the table. After this routine returns, ** the root page is empty, but still exists. *** This routine will fail with SQLITE_LOCKED if there are any open ** read cursors on the table. Open write cursors are moved to the ** root of the table. *** If pnChange is not NULL, then table iTTable must be an intkey table. The ** integer value pointed to by pnChange is incremented by the number of ** entries in the table.

77601. The function name.

77602. Fetch the integer off the end of the index record

77603. Restriction (15)
77604. Automatic indexes
77605. BTree containing table to open
77606. Generated temporary filenames are always double-zero terminated ** for use by sqlite3_uri_parameter().
77607. Block id of first leaf node
77608. The Table object to which the virtual table belongs
77609. (303) oneselect ::= values
77610. VDBE cursor that is the main data repository
77611. True after sqlite3_declare_vtab() is called
77612. The X==Ei expression
77613. Search for a page near this one
77614. ** Open the file zPath. ** ** Previously, the SQLite OS layer used three functions in place of this ** one: ** ** sqlite3OsOpenReadWrite(); ** sqlite3OsOpenReadOnly(); ** sqlite3OsOpenExclusive(); ** ** These calls correspond to the following combinations of flags: ** ** ReadWrite() -> (READWRITE | CREATE) ** ReadOnly() -> (READONLY) ** OpenExclusive() -> (READWRITE | CREATE | EXCLUSIVE) ** ** The old OpenExclusive() accepted a boolean argument - "delFlag". If ** true, the file was configured to be automatically deleted when the ** file handle closed. To achieve the same effect using this new ** interface, add the DELETEONCLOSE flag to those specified above for ** OpenExclusive().
77615. Set the EP_Reduced, EP_TokenOnly, and EP_Static flags appropriately.
77616. Replacement expressions
77617. Indexed column is the rowid
77618. The main parser program. ** The first argument is a pointer to a structure obtained from ** "sqlite3Fts5ParserAlloc" which describes the current state of the parser. ** The second argument is the major token number. The third is ** the minor token. The fourth optional argument is whatever the ** user wants (and specified in the grammar) and is available for ** use by the action routines. ** ** Inputs: ** ** A pointer to the parser (an opaque structure.) ** The major token number. ** The minor token number. ** An option argument of a grammar-specified type. ** ** ** Outputs: ** None.
77619. Generate code to query the parent index for a matching parent ** key. If a match is found, jump to addrOk.
77620. Simple "PRAGMA locking_mode;" statement. This is a query for ** the current default locking mode (which may be different to ** the locking-mode of the main database).
77621. True if EXPLAIN present on SQL command
77622. 38
77623. ** sqlite3_test_control(SQLITE_TESTCTRL_BYTORDER); ** ** The integer returned reveals the byte-order of the computer on which ** SQLite is running: ** ** 1 big-endian, determined at run-time ** 10 little-endian, determined at run-time ** 432101 big-endian, determined at compile-time ** 123410 little-endian, determined at compile-time
77624. Path of the file to examine
77625. If nIncr is less than zero, then check at runtime if there are any ** outstanding constraints to resolve. If there are not, there is no need ** to check if deleting this row resolves any outstanding violations. ** ** Check if any of the key columns in the child table row are NULL. If ** any are, then the constraint is considered satisfied. No need to ** search for a matching row in the parent table.
77626. 'occurrences' values for current csr row
77627. Not a recursive common table expression.
77628. Deleted OK.
77629. The root page of the table to be locked
77630. New aRegion[] array
77631. This could happen with a network mount
77632. tcons ::= FOREIGN KEY LP eidlist RP REFERENCES nm eidlist_opt refargs defer_subclause_opt
77633. The "langid = ?" constraint, if any
77634. 990
77635. Space to hold the virtual machine's program
77636. If the statement journal is open and the page is not in it, ** then write the page into the statement journal.
77637. Store results here
77638. ** Called by the parser to compile a DETACH statement. ** ** DETACH pDname
77639. Address of the A<B subroutine
77640. ** Write out a single frame of the WAL
77641. Declare and initialize constant integer 'isDirect'. If the ** atomic-write optimization is enabled in this build, then isDirect ** is initialized to the value passed as the isDirectMode parameter ** to this function. Otherwise, it is always set to zero. ** ** The idea is that if the atomic-write optimization is not ** enabled at compile time, the compiler can omit the tests of ** 'isDirect' below, as well as the block enclosed in the ** "if(isDirect)" condition.
77642. Mutex type
77643. Size of vector pLeft
77644. ** CAPI3REF: Set the Last Insert Rowid value. ** METHOD: sqlite3 ** ** The sqlite3_set_last_insert_rowid(D, R) method allows the application to ** set the value returned by calling sqlite3_last_insert_rowid(D) to R ** without inserting a row into the database.
77645. ** Exit the recursive mutex on a Btree.
77646. At this point variable c contains the first character of the ** pattern string past the "**". Search in the input string for the ** first matching character and recursively continue the match from ** that point. ** ** For a case-insensitive search, set variable cx to be the same as ** c but in the other case and search the input string for either ** c or cx.
77647. testcase(IS_BIG_INT(iOffset)); // requires a 4GiB WAL file
77648. Maximum bytes of data to store
77649. Type passed as 4th argument to SegmentReaderIterate()
77650. ** The following macros are used to cast pointers to integers and ** integers to pointers. The way you do this varies from one compiler ** to the next, so we have developed the following set of #if statements ** to generate appropriate macros for a wide range of compilers. ** ** The correct "ANSI" way to do this is to use the intptr_t type. ** Unfortunately, that typedef is not available on all compilers, or ** if it is available, it requires an #include of specific headers ** that vary from one machine to the next. ** ** Ticket #3860: The llvm-gcc-4.2 compiler from Apple chokes on ** the ((void*)&((char*)0)[X]) construct. But MSVC chokes on ((void*)(X)). ** So we have to define the macros in different ways depending on the ** compiler.
77651. If the file format and encoding in the database have not been set, ** set them now.
77652. SQLITE_SO_ASC or SQLITE_SO_DESC
77653. Merge engine to return
77654. Deal with as much of this read request as possible by transferring ** data from the memory mapping using memcpy().
77655. Address of next instruction to return
77656. Root page of table to open
77657. We will need to create our own temporary table to hold the ** intermediate results.
77658. 241
77659. Mem.eSubtype is valid
77660. An index we are evaluating
77661. expr ::= ID|INDEXED LP distinct exprlist RP
77662. ** Information about the current state of the WAL file and where ** the next fsync should occur - passed from sqlite3WalFrames() into ** walWriteToLog().
77663. So that sizeof(Mem) is a multiple of 8
77664. Rows processed for all objects
77665. OUT: Error code
77666. Determine the number of integers in the buffer returned by this call.
77667. ** CAPI3REF: Compile-Time Authorization Callbacks ** METHOD: sqlite3 ** KEYWORDS: {authorizer callback} ** ** ^This routine registers an authorizer callback with a particular ** [database connection], supplied in the first argument. ** ^The authorizer callback is invoked as SQL statements are being compiled ** by [sqlite3_prepare()] or its variants [sqlite3_prepare_v2()], ** [sqlite3_prepare_v3()], [sqlite3_prepare16()], [sqlite3_prepare16_v2()], ** and

[sqlite3_prepare16_v3()]. ^At various ** points during the compilation process, as logic is being created ** to perform various actions, the authorizer callback is invoked to ** see if those actions are allowed. ^The authorizer callback should ** return [SQLITE_OK] to allow the action, [SQLITE_IGNORE] to disallow the ** specific action but allow the SQL statement to continue to be ** compiled, or [SQLITE_DENY] to cause the entire SQL statement to be ** rejected with an error. ^If the authorizer callback returns ** any value other than [SQLITE_IGNORE], [SQLITE_OK], or [SQLITE_DENY] ** then the [sqlite3_prepare_v2()] or equivalent call that triggered ** the authorizer will fail with an error message. *** When the callback returns [SQLITE_OK], that means the operation ** requested is ok. ^When the callback returns [SQLITE_DENY], the ** [sqlite3_prepare_v2()] or equivalent call that triggered the ** authorizer will fail with an error message explaining that ** access is denied. *** ^The first parameter to the authorizer callback is a copy of the third ** parameter to the sqlite3_set_authorizer() interface. ^The second parameter ** to the callback is an integer [SQLITE_COPY | action code] that specifies ** the particular action to be authorized. ^The third through sixth parameters ** to the callback are either NULL pointers or zero-terminated strings ** that contain additional details about the action to be authorized. ** Applications must always be prepared to encounter a NULL pointer in any ** of the third through the sixth parameters of the authorization callback. *** ^If the action code is [SQLITE_READ] ** and the callback returns [SQLITE_IGNORE] then the ** [prepared statement] statement is constructed to substitute ** a NULL value in place of the table column that would have ** been read if [SQLITE_OK] had been returned. The [SQLITE_IGNORE] ** return can be used to deny an untrusted user access to individual ** columns of a table. *** ^When a table is referenced by a [SELECT] but no column values are ** extracted from that table (for example in a query like ** "SELECT count(*) FROM tab") then the [SQLITE_READ] authorizer callback ** is invoked once for that table with a column name that is an empty string. ** ^If the action code is [SQLITE_DELETE] and the callback returns ** [SQLITE_IGNORE] then the [DELETE] operation proceeds but the ** [truncate optimization] is disabled and all rows are deleted individually. *** An authorizer is used when [sqlite3_prepare | preparing] ** SQL statements from an untrusted source, to ensure that the SQL statements ** do not try to access data they are not allowed to see, or that they do not ** try to execute malicious statements that damage the database. For ** example, an application may allow a user to enter arbitrary ** SQL queries for evaluation by a database. But the application does ** not want the user to be able to make arbitrary changes to the ** database. An authorizer could then be put in place while the ** user-entered SQL is being [sqlite3_prepare | prepared] that ** disallows everything except [SELECT] statements. *** Applications that need to process SQL from untrusted sources ** might also consider lowering resource limits using [sqlite3_limit()] ** and limiting database size using the [max_page_count] [PRAGMA] ** in addition to using an authorizer. *** ^Only a single authorizer can be in place on a database connection ** at a time. Each call to sqlite3_set_authorizer overrides the ** previous call.^A ^Disable the authorizer by installing a NULL callback. ** The authorizer is disabled by default. *** ^The authorizer callback must not do anything that will modify ** the database connection that invoked the authorizer callback. ** Note that [sqlite3_prepare_v2()] and [sqlite3_step()] both modify their ** database connections for the meaning of "modify" in this paragraph. *** ^When [sqlite3_prepare_v2()] is used to prepare a statement, the ** statement might be re-prepared during [sqlite3_step()] due to a ** schema change. Hence, the application should ensure that the ** correct authorizer callback remains in place during the [sqlite3_step()]. *** ^Note that the authorizer callback is invoked only during ** [sqlite3_prepare()] or its variants. Authorization is not ** performed during statement evaluation in [sqlite3_step()], unless ** as stated in the previous paragraph, sqlite3_step() invokes ** sqlite3_prepare_v2() to reprepare a statement after a schema change.

77668. All collating sequences

77669. **comment:** ** This function is called when the user executes the following statement: ** ** INSERT INTO <tbl><tbl> VALUES('rebuild'); ** ** The entire FTS index is discarded and rebuilt. If the table is one ** created using the content=xxx option, then the new index is based on ** the current contents of the xxx table.

label: code-design

77670. Cursor number of the first index

77671. **comment:** ** Macros for performance tracing. Normally turned off. Only works ** on i486 hardware.

label: code-design

77672. Mutex to access this object

77673. Used to catch return codes

77674. ** Process statements of the form: ** ** INSERT INTO table(table) VALUES('automerge=X'); ** ** where X is an integer. X==0 means to turn automerge off. X!=0 means ** turn it on. The setting is persistent.

77675. **comment:** Size of the temporary register block

label: code-design

77676. Language being queried

77677. ** If defined as non-zero, auto-vacuum is enabled by default. Otherwise ** it must be turned on for each database using "PRAGMA auto_vacuum = 1".

77678. True if this expression is entirely deferred

77679. Integer value of right operand

77680. Attach the hook to this database

77681. ** The functions querySharedCacheTableLock(), setSharedCacheTableLock(), ** and clearAllSharedCacheTableLocks() ** manipulate entries in the BtShared.pLock linked list used to store ** shared-cache table level locks. If the library is compiled with the ** shared-cache feature disabled, then there is only ever one user ** of each BtShared structure and so this locking is not necessary. ** So define the lock related functions as no-ops.

77682. ** Rtree virtual table module xDestroy method.

77683. Array of nCol best samples

77684. Index of column matching zCol

77685. Make sure this analysis did not leave any unref() pages.

77686. All unixShm objects pointing to this

77687. ** Implementation of SQL scalar function rbu_fossil_delta(). ** ** This function applies a fossil delta patch to a blob. Exactly two ** arguments must be passed to this function. The first is the blob to ** patch and the second the patch to apply. If no error occurs, this ** function returns the patched blob.

77688. Only interested in == results

77689. Hash slot index

77690. No more tokens here

77691. ** Deserialize cell iCell of node pNode. Populate the structure pointed ** to by pCell with the results.

77692. synopsis: if r[P3] in rowset(P1) goto P2

77693. 206

77694. The following loop runs once for each term in a compound-subquery ** flattening (as described above). If we are doing a different kind ** of flattening - a flattening other than a compound-subquery flattening - ** then this loop only runs once. *** This loop moves all of the FROM elements of the subquery into the ** the FROM clause of the outer query. Before doing this, remember ** the cursor number for the original outer query FROM element in ** iParent. The iParent cursor will never be used. Subsequent code ** will scan expressions looking for iParent references and replace ** those references with expressions that resolve to the subquery FROM ** elements we are now copying in.

77695. **comment:** ** This division contains definitions of sqlite3_io_methods objects that ** implement various file locking strategies. It also contains definitions ** of "finder" functions. A finder-function is used to locate the appropriate ** sqlite3_io_methods object for a particular database file. The pAppData ** field of the sqlite3_vfs objects are initialized to be pointers to ** the correct finder-function for that VFS. *** Most finder functions return a pointer to a fixed sqlite3_io_methods ** object. The only interesting finder-function is autolockIoFinder, which ** looks at the filesystem type and tries to guess the best locking ** strategy from that. *** For finder-function F, two objects are created: *** (1) The real finder-function named "FImpt()". *** (2) A constant pointer to this function named just "F". *** A pointer to the F pointer is used as the pAppData value for VFS ** objects. We have to do this instead of letting pAppData point ** directly at the finder-function since C90 rules prevent a void* ** from be cast into a function pointer. *** Each instance of this macro generates two objects: *** * A constant sqlite3_io_methods object call METHOD that has locking ** methods CLOSE, LOCK, UNLOCK, CKRESLOCK. *** * An I/O method finder function called FINDER that returns a pointer ** to the METHOD object in the previous bullet.

label: code-design

77696. ** Try to convert the type of a function argument or a result column ** into a numeric representation. Use either INTEGER or REAL whichever ** is appropriate. But only do the conversion if it is possible without ** loss of information and return the revised type of the argument.

77697. Pointer to <id> token

77698. **comment:** If we are just shaving the last few pages off the end of the ** cache, then there is no point in scanning the entire hash table. ** Only scan those hash slots that might contain pages that need to ** be removed.

77700. Name of fts3 table

77701. If shifting by a negative amount, shift in the other direction

77702. ** Added after 3.3.13
77703. Name of file to check
77704. MSVC is picky about pulling func ptrs from va lists. ** http://support.microsoft.com/kb/47961 ** sqlite3GlobalConfig.xLog = va_arg(ap, void*)(void*,int,const char*);
77705. WHERE_GROUPBY or _DISTINCTBY or _ORDERBY_LIMIT
77706. ** This is defined in tokenize.c. We just have to import the definition.
77707. Value to append
77708. xCreate/xConnect argument array
77709. ** The following value as a destructor means to use sqlite3DbFree(). ** The sqlite3DbFree() routine requires two parameters instead of the ** one parameter that destructors normally want. So we have to introduce ** this magic value that the code knows to handle differently. Any ** pointer will work here as long as it is distinct from SQLITE_STATIC ** and SQLITE_TRANSIENT.
77710. Size of zBlob in bytes
77711. The VDBE cursor
77712. in2: P2 is an input
77713. figure out how many UTF-8 characters are in zName
77714. ** The following are the meanings of bits in the Expr.flags field.
77715. True if this is a patchset
77716. Return code of various sub-routines
77717. ** Implementation of the scalar function fts3_tokenizer_internal_test(). ** This function is used for testing only, it is not included in the ** build unless SQLITE_TEST is defined. ** ** The purpose of this is to test that the fts3_tokenizer() function ** can be used as designed by the C-code in the queryTokenizer and ** registerTokenizer() functions above. These two functions are repeated ** in the README.tokenizer file as an example, so it is important to ** test them. ** ** To run the tests, evaluate the fts3_tokenizer_internal_test() scalar ** function with no arguments. An assert() will fail if a problem is ** detected. i.e.: ** ** SELECT fts3_tokenizer_internal_test(); **
77718. Lock the source database handle. The destination database ** handle is not locked in this routine, but it is locked in ** sqlite3_backup_step(). The user is required to ensure that no ** other thread accesses the destination handle for the duration ** of the backup operation. Any attempt to use the destination ** database connection while a backup is in progress may cause ** a malfunction or a deadlock.
77719. joinop ::= JOIN_KW nm nm JOIN
77720. transitive constraints
77721. The fields of the result
77722. ** CAPI3REF: Virtual Table Interface Configuration ** ** This function may be called by either the [xConnect] or [xCreate] method ** of a [virtual table] implementation to configure ** various facets of the virtual table interface. ** ** If this interface is invoked outside the context of an xConnect or ** xCreate virtual table method then the behavior is undefined. ** ** At present, there is only one option that may be configured using ** this function. (See [SQLITE_VTAB_CONSTRAINT_SUPPORT].) Further options ** may be added in the future.
77723. Path to target db
77724. Database file path
77725. Buffer containing page-index
77726. # include <time.h>
77727. The comparison operation
77728. First rowid on leaf iLeafPgno
77729. Flags to use to sync header writes
77730. ** Write VDBE code to erase table pTab and all associated indices on disk. ** Code to update the sqlite_master tables and internal schema definitions ** in case a root-page belonging to another table is moved by the btree layer ** is also added (this can happen with an auto-vacuum database).
77731. ** CAPI3REF: Virtual File System Objects ** ** A virtual filesystem (VFS) is an [sqlite3_vfs] object ** that SQLite uses to interact ** with the underlying operating system. Most SQLite builds come with a ** single default VFS that is appropriate for the host computer. ** New VFSes can be registered and existing VFSes can be unregistered. ** The following interfaces are provided. ** ** ^The sqlite3_vfs_find() interface returns a pointer to a VFS given its name. ** ^Names are case sensitive. ** ^Names are zero-terminated UTF-8 strings. ** ^If there is no match, a NULL pointer is returned. ** ^If zVfsName is NULL then the default VFS is returned. ** ** ^New VFSes are registered with sqlite3_vfs_register(). ** ^Each new VFS becomes the default VFS if the makeDflt flag is set. ** ^The same VFS can be registered multiple times without injury. ** ^To make an existing VFS into the default VFS, register it again ** with the makeDflt flag set. If two different VFSes with the ** same name are registered, the behavior is undefined. If a ** VFS is registered with a name that is NULL or an empty string, ** then the behavior is undefined. ** ** ^Unregister a VFS with the sqlite3_vfs_unregister() interface. ** ^^(If the default VFS is unregistered, another VFS is chosen as ** the default. The choice for the new VFS is arbitrary.)^
77732. Used when p4type is P4_VTAB
77733. Advance iterator at least this far
77734. Configuration object
77735. Flush the last leaf page to disk. Set the output segment b-tree height ** and last leaf page number at the same time.
77736. If a rowid value was supplied, check if it is already present in ** the table. If so, the constraint has failed.
77737. ** Mark every prepared statement associated with a database connection ** as expired. ** ** An expired statement means that recompilation of the statement is ** recommend. Statements expire when things happen that make their ** programs obsolete. Removing user-defined functions or collating ** sequences, or changing an authorization function are the types of ** things that make prepared statements obsolete.
77738. 134
77739. Database page-size
77740. The name context cannot be NULL.

77755. One table in the FROM clause
77756. The virtual table being constructed
77757. Linked list of auxdata allocations
77758. Obtain an exclusive lock on all byte in the locking range not already ** locked by the caller. The caller is guaranteed to have locked the ** WAL_WRITE_LOCK byte, and may have also locked the WAL_CKPT_LOCK byte. ** If successful, the same bytes that are locked here are unlocked before ** this function returns.
77759. Number of entries with this hash

77760. True if holding the unixShmNode mutex
77761. expr ::= nm DOT nm
77762. Used to iterate through VMs
77763. INSERT or UPDATE operations
77764. ** Open a handle to begin or resume an RBU VACUUM operation.
77765. Check all the tables.
77766. Boolean parameters. See BTS_* macros below
77767. Fts5 context
77768. Read input from all segments in the input level
77769. ** This object represents a single thread of control in a sort operation. ** Exactly VdbeSorter.nTask instances of this object are allocated ** as part of each VdbeSorter object. Instances are never allocated any ** other way. VdbeSorter.nTask is set to the number of worker threads allowed ** (see SQLITE_CONFIG_WORKER_THREADS) plus one (the main thread). Thus for ** single-threaded operation, there is exactly one instance of this object ** and for multi-threaded operation there are two or more instances. ** ** Essentially, this structure contains all those fields of the VdbeSorter ** structure for which each thread requires a separate instance. For example, ** each thread requires its own UnpackedRecord object to unpack records in ** as part of comparison operations. ** ** Before a background thread is launched, variable bDone is set to 0. Then, ** right before it exits, the thread itself sets bDone to 1. This is used for ** two purposes: ** ** 1. When flushing the contents of memory to a level-0 PMA on disk, to ** attempt to select a SortSubtask for which there is not already an ** active background thread (since doing so causes the main thread ** to block until it finishes). ** ** 2. If SQLITE_DEBUG_SORTER_THREADS is defined, to determine if a call ** to sqlite3ThreadJoin() is likely to block. Cases that are likely to ** block provoke debugging output. ** ** In both cases, the effects of the main thread seeing (bDone==0) even ** after the thread has finished are not dire. So we don't worry about ** memory barriers and such here.
77770. If pTab is really a view, make sure it has been initialized.
77771. WinRT has no way to convert a relative path to an absolute one.
77772. First frame that may be overwritten
77773. OUT: New iterator object

77776. Opcode: Rowid P1 P2 * * * ** Synopsis: r[P2]=rowid ** ** Store in register P2 an integer which is the key of the table entry that ** P1 is currently point to. ** ** P1 can be either an ordinary table or a virtual table. There used to ** be a separate OP_VRowid opcode for use with virtual tables, but this ** one opcode now works for both table types.
77777. Allocate a MultiSegReader for each token in the expression.
77778. Allocate additional space if needed
77779. Array containing doclist (or NULL)
77780. 244
77781. Pointer to cursor object to return
77782. ** This routine is the only routine in this file with external ** linkage. ** ** Populate the low-level memory allocation function pointers in ** sqlite3GlobalConfig.m with pointers to the routines in this file. The ** arguments specify the block of memory to manage. ** ** This routine is only called by sqlite3_config(), and therefore ** is not required to be threadsafe (it is not).
77783. Name context of this SELECT
77784. Variables related to SQLITE_CONFIG_PAGECACHE settings. The ** szSlot, nSlot, pStart, pEnd, nReserve, and isInit values are all ** fixed at sqlite3_initialize() time and do not require mutex protection. ** The nFreeSlot and pFree values do require mutex protection.
77785. EVIDENCE-OF: R-29851-52272 Value is a big-endian 64-bit ** two-complement integer.
77786. If needSyncPnno is non-zero, then the journal file needs to be ** sync(jed before any data is written to database file page needSyncPnno. ** Currently, no such page exists in the page-cache and the ** "is journaled" bitvec flag has been set. This needs to be remedied by ** loading the page into the pager-cache and setting the PGHDR_NEED_SYNC ** flag. ** ** If the attempt to load the page into the page-cache fails, (due ** to a malloc() or IO failure), clear the bit in the pInJournal[] ** array. Otherwise, if the page is loaded and written again in ** this transaction, it may be written to the database file before ** it is synced into the journal file. This way, it may end up in ** the journal file twice, but that is not a problem.
77787. Resolve all names in the ORDER BY term expression
77788. ** Seek to the offset in id->offset then read cnt bytes into pBuf. ** Return the number of bytes actually read. Update the offset. ** ** To avoid stomping the errno value on a failed write the lastErrno value ** is set before returning.
77789. ** Implementation of xBegin() method.
77790. Rowid for this entry
77791. **comment:** ** 2004 April 6 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** This file implements an external (disk-based) database using BTrees. ** For a detailed discussion of BTrees, refer to ** ** Donald E. Knuth, THE ART OF COMPUTER PROGRAMMING, Volume 3: ** "Sorting And Searching", pages 473-480. Addison-Wesley ** Publishing Company, Reading, Massachusetts. ** ** The basic idea is that each page of the file contains N database ** entries and N+1 pointers to subpages. ** ** ----- ** | Ptr(0) | Key(0) | Ptr(1) | Key(1) | ... | Key(N-1) | Ptr(N) | ** ----- ** All of the keys on the page that Ptr(0) points to have values less ** than Key(0). All of the keys on page Ptr(1) and its subpages have ** values greater than Key(0) and less than Key(1). All of the keys ** on Ptr(N) and its subpages have values greater than Key(N-1). And ** so forth. ** ** Finding a particular key requires reading O(log(M)) pages from the ** disk where M is the number of entries in the tree. ** ** In this implementation, a single file can hold one or more separate ** BTrees. Each BTree is identified by the index of its root page. The ** key and data for any entry are combined to form the "payload". A ** fixed amount of payload can be carried directly on the database ** page. If the payload is larger than the preset amount then surplus ** bytes are stored on overflow pages. The payload for an entry ** and the preceding pointer are combined to form a "Cell". Each ** page has a small header which contains the Ptr(N) pointer and other ** information such as the size of key and data. ** ** FORMAT DETAILS ** ** The file is divided into pages. The first page is called page 1, ** the second is page 2, and so forth. A page number of zero indicates ** "no such page". The page size can be any power of 2 between 512 and 65536. ** Each page can be either a btree page, a freelist page, an overflow ** page, or a pointer-map page. ** ** The first page is always a btree page. The first 100 bytes of the first ** page contain a special header (the "file header") that describes the file. ** The format of the file header is as follows: ** ** OFFSET SIZE DESCRIPTION ** 0 16 Header string: "SQLite format 3|000" ** 16 2 Page size in bytes. (1 means 65536) ** 18 1 File format write version ** 19 1 File format read version ** 20 1 Bytes of unused space at the end of each page ** 21 1 Max embedded payload fraction (must be 64) ** 22 1 Min embedded payload fraction (must be 32) ** 23 1 Min leaf payload fraction (must be 32) ** 24 4 File change counter ** 28 4 Reserved for future use ** 32 4 First freelist page ** 36 4 Number of freelist pages in the file ** 40 60 15 4-byte meta values passed to higher layers ** ** 40 4 Schema cookie ** 44 4 File format of schema layer ** 48 4 Size of page cache ** 52 4 Largest root-page (auto/incr_vacuum) ** 56 4 1=UTF-8 2=UTF16le 3=UTF16be ** 60 4 User version ** 64 4 Incremental vacuum mode ** 68 4 Application-ID ** 72 20 unused ** 92 4 The version-valid-for number ** 96 4 SQLITE_VERSION_NUMBER ** ** All of the integer values are big-endian (most significant byte first). ** ** The file change counter is incremented when the database is changed ** This counter allows other processes to know when the file has changed ** and thus when they need to flush their cache. ** ** The max embedded payload fraction is the amount of the total usable ** space in a page that can be consumed by a single cell for standard ** B-tree (non-LEAFDATA) tables. A value of 255 means 100%. The default ** is to limit the maximum cell size so that at least 4 cells will fit ** on one page. Thus the default max embedded payload fraction is 64. ** ** If the payload for a cell is larger than the max payload, then extra ** payload is spilled to overflow pages. Once an overflow page is allocated, ** as many bytes as possible are moved into the overflow pages without letting ** the cell size drop below the min embedded payload fraction. ** ** The min leaf payload fraction is like the min embedded payload fraction ** except that it applies to leaf nodes in a LEAFDATA tree. The maximum ** payload fraction for a LEAFDATA tree is always 100% (or 255) and it ** not specified in the header. ** ** Each btree pages is divided into three sections: The header, the ** cell pointer array, and the cell content area. Page 1 also has a 100-byte ** file header that occurs before the page header. ** ** ----- ** | file header | 100 bytes. Page 1 only. ** | ----- | ** | page header | 8 bytes for leaves. 12 bytes for interior nodes ** |-----| ** | cell pointer | 2 bytes per cell. Sorted order. ** | array | | Grows downward ** | | v ** |-----| ** | unallocated | ** | space | ** |-----| ^ Grows upwards ** | cell content | | Arbitrary order interspersed with freeblocks. ** | area | | and free space fragments. ** |-----| ** ** The page headers looks like this. ** ** OFFSET SIZE DESCRIPTION ** 0 1 Flags. 1: intkey, 2: zerodata, 4: leafdata, 8: leaf ** 1 2 byte offset to the first freeblock ** 3 2 number of cells on this page ** 5 2 first byte of the cell content area ** 7 1 number of fragmented free bytes ** 8 4 Right child (the Ptr(N) value). Omitted on leaves. ** ** The flags define the format of this btree page. The leaf flag means that ** this page has no children. The zerodata flag means that this page carries ** only keys and no data. The intkey flag means that the key is an integer ** which is stored in the key size entry of the cell header rather than in ** the payload area. ** ** The cell pointer array begins on the first byte after the page header. ** The cell pointer array

contains zero or more 2-byte numbers which are ** offsets from the beginning of the page to the cell content in the cell ** content area. The cell pointers occur in sorted order. The system strives ** to keep free space after the last cell pointer so that new cells can ** be easily added without having to defragment the page. ** ** Cell content is stored at the very end of the page and grows toward the ** beginning of the page. ** ** Unused space within the cell content area is collected into a linked list of ** freeblocks. Each freeblock is at least 4 bytes in size. The byte offset ** to the first freeblock is given in the header. Freeblocks occur in ** increasing order. Because a freeblock must be at least 4 bytes in size, ** any group of 3 or fewer unused bytes in the cell content area cannot ** exist on the freeblock chain. A group of 3 or fewer free bytes is called ** a fragment. The total number of bytes in all fragments is recorded. ** in the page header at offset 7. ** ** SIZE DESCRIPTION ** 2 Byte offset of the next freeblock ** 2 Bytes in this freeblock ** ** Cells are of variable length. Cells are stored in the cell content area at ** the end of the page. Pointers to the cells are in the cell pointer array ** that immediately follows the page header. Cells is not necessarily ** contiguous or in order, but cell pointers are contiguous and in order. ** ** Cell content makes use of variable length integers. A variable ** length integer is 1 to 9 bytes where the lower 7 bits of each ** byte are used. The integer consists of all bytes that have bit 8 set and ** the first byte with bit 8 clear. The most significant byte of the integer ** appears first. A variable-length integer may not be more than 9 bytes long. ** As a special case, all 8 bytes of the 9th byte are used as data. This ** allows a 64-bit integer to be encoded in 9 bytes. ** ** 0x00 becomes 0x00000000 ** 0x7f becomes 0x00000007f ** 0x81 0x00 becomes 0x00000080 ** 0x82 0x00 becomes 0x00000100 ** 0x80 0x7f becomes 0x0000007f ** 0x8a 0x91 0xd1 0xac 0x78 becomes 0x12345678 ** 0x81 0x81 0x81 0x81 0x01 becomes 0x10204081 ** ** Variable length integers are used for rowids and to hold the number of ** bytes of key and data in a btree cell. ** ** The content of a cell looks like this: ** ** SIZE DESCRIPTION ** 4 Page number of the left child. Omitted if leaf flag is set. ** var Number of bytes of data. Omitted if the zerodata flag is set. ** var Number of bytes of key. Or the key itself if intkey flag is set. ** * Payload ** 4 First page of the overflow chain. Omitted if no overflow ** ** Overflow pages form a linked list. Each page except the last is completely ** filled with data (pagesize - 4 bytes). The last page can have as little ** as 1 byte of data. ** ** SIZE DESCRIPTION ** 4 Page number of next overflow page ** * Data ** ** Freelist pages come in two subtypes: trunk pages and leaf pages. The ** file header points to the first in a linked list of trunk page. Each trunk ** page points to multiple leaf pages. The content of a leaf page is ** unspecified. A trunk page looks like this: ** ** SIZE DESCRIPTION ** 4 Page number of next trunk page ** 4 Number of leaf pointers on this page ** * zero or more pages numbers of leaves

***** * This file implements an object that represents a fixed-length ** bitmap. Bits are numbered starting with 1. *** A bitmap is used to record which pages of a database file have been ** journaled during a transaction, or which pages have the "dont-write" ** property. Usually only a few pages are meet either condition. ** So the bitmap is usually sparse and has low cardinality. ** But sometimes (for example when during a DROP of a large table) most ** or all of the pages in a database can get journaled. In those cases, ** the bitmap becomes dense with high cardinality. The algorithm needs ** to handle both cases well. *** The size of the bitmap is fixed when the object is created. *** All bits are clear when the bitmap is created. Individual bits ** may be set or cleared one at a time. *** Test operations are about 100 times more common than set operations. ** Clear operations are exceedingly rare. There are usually between ** 5 and 500 set operations per Bitvec object, though the number of sets can ** sometimes grow into tens of thousands or larger. The size of the ** Bitvec object is the number of pages in the database file at the ** start of a transaction, and is thus usually less than a few thousand, ** but can be as large as 2 billion for a really big database.

label: code-design

78308. ** Each foreign key constraint is an instance of the following structure. *** A foreign key is associated with two tables. The "from" table is ** the table that contains the REFERENCES clause that creates the foreign ** key. The "to" table is the table that is named in the REFERENCES clause. ** Consider this example: *** CREATE TABLE ex1(** a INTEGER PRIMARY KEY, ** b INTEGER CONSTRAINT fk1 REFERENCES ex2(x)); *** For foreign key "fk1", the from-table is "ex1" and the to-table is "ex2". ** Equivalent names: *** from-table == child-table ** to-table == parent-table *** Each REFERENCES clause generates an instance of the following structure ** which is attached to the from-table. The to-table need not exist when ** the from-table is created. The existence of the to-table is not checked. *** The list of all parents for child Table X is held at X.pfKey. *** A list of all children for a table named Z (which might not even exist) ** is held in Schema.fkeyHash with a hash key of Z.

78309. **comment:** ** An open page cache is an instance of struct Pager. A description of ** some of the more important member variables follows: *** eState *** The current 'state' of the pager object. See the comment and state ** diagram above for a description of the pager state. *** eLock *** For a real on-disk database, the current lock held on the database file - ** NO_LOCK, SHARED_LOCK, RESERVED_LOCK or EXCLUSIVE_LOCK. *** For a temporary or in-memory database (neither of which require any ** locks), this variable is always set to EXCLUSIVE_LOCK. Since such ** databases always have Pager.exclusiveMode==1, this tricks the pager ** logic into thinking that it already has all the locks it will ever ** need (and no reason to release them). *** In some (obscure) circumstances, this variable may also be set to ** UNKNOWN_LOCK. See the comment above the #define of UNKNOWN_LOCK for ** details. *** changeCountDone *** This boolean variable is used to make sure that the change-counter ** (the 4-byte header field at byte offset 24 of the database file) is ** not updated more often than necessary. *** It is set to true when the change-counter field is updated, which ** can only happen if an exclusive lock is held on the database file. *** It is cleared (set to false) whenever an exclusive lock is ** relinquished on the database file. Each time a transaction is committed, ** The changeCountDone flag is inspected. If it is true, the work of ** updating the change-counter is omitted for the current transaction. *** This mechanism means that when running in exclusive mode, a connection ** need only update the change-counter once, for the first transaction ** committed. *** setMaster *** When PagerCommitPhaseOne() is called to commit a transaction, it may ** (or may not) specify a master-journal name to be written into the ** journal file before it is synced to disk. *** Whether or not a journal file contains a master-journal pointer affects ** the way in which the journal file is finalized after the transaction is ** committed or rolled back when running in "journal_mode=PERSIST" mode. ** If a journal file does not contain a master-journal pointer, it is ** finalized by overwriting the first journal header with zeroes. If ** it does contain a master-journal pointer the journal file is finalized ** by truncating it to zero bytes, just as if the connection were ** running in "journal_mode=truncate" mode. *** Journal files that contain master journal pointers cannot be finalized ** simply by overwriting the first journal-header with zeroes, as the ** master journal pointer could interfere with hot-journal rollback of any ** subsequently interrupted transaction that reuses the journal file. *** The flag is cleared as soon as the journal file is finalized (either ** by PagerCommitPhaseTwo or PagerRollback). If an IO error prevents the ** journal file from being successfully finalized, the setMaster flag ** is cleared anyway (and the pager will move to ERROR state). *** doNotSpill *** This variables control the behavior of cache-spills (calls made by ** the pcache module to the pagerStress() routine to write cached data ** to the file-system in order to free up memory). *** When bits SPILLFLAG_OFF or SPILLFLAG_ROLLBACK of doNotSpill are set, ** writing to the database from pagerStress() is disabled altogether. ** The SPILLFLAG_ROLLBACK case is done in a very obscure case that ** comes up during savepoint rollback that requires the pcache module ** to allocate a new page to prevent the journal file from being written ** while it is being traversed by code in pager_playback(). The SPILLFLAG_OFF ** case is a user preference. *** If the SPILLFLAG_NOSYNC bit is set, writing to the database from ** pagerStress() is permitted, but syncing the journal file is not. ** This flag is set by sqlite3PagerWrite() when the file-system sector-size ** is larger than the database page-size in order to prevent a journal sync ** from happening in between the journaling of two pages on the same sector. *** subJInMemory *** This is a boolean variable. If true, then any required sub-journal ** is opened as an in-memory journal file. If false, then in-memory ** sub-journals are only used for in-memory pager files. *** This variable is updated by the upper layer each time a new ** write-transaction is opened. *** dbSize, dbOrigSize, dbFileSize *** Variable dbSize is set to the number of pages in the database file. ** It is valid in PAGER_READER and higher states (all states except for ** OPEN and ERROR). *** dbSize is set based on the size of the database file, which may be ** larger than the size of the database (the value stored at offset ** 28 of the database header by the btree). If the size of the file ** is not an integer multiple of the page-size, the value stored in ** dbSize is rounded down (i.e. a 5KB file with 2K page-size has dbSize==2). ** Except, any file that is greater than 0 bytes in size is considered ** to have at least one page. (i.e. a 1KB file with 2K page-size leads ** to dbSize==1). *** During a write-transaction, if pages with page-numbers greater than ** dbSize are modified in the cache, dbSize is updated accordingly. ** Similarly, if the database is truncated using PagerTruncateImage(), ** dbSize is updated. *** Variables dbOrigSize and dbFileSize are valid in states ** PAGER_WRITER_LOCKED and higher. dbOrigSize is a copy of the dbSize ** variable at the start of the transaction. It is used during rollback, ** and to determine whether or not pages need to be journalled before ** being modified. *** Throughout a write-transaction, dbFileSize contains the size of ** the file on disk in pages. It is set to a copy of dbSize when the ** write-transaction is first opened, and updated when VFS calls are made ** to write or truncate the database file on disk. *** The only reason the dbFileSize variable is required is to suppress ** unnecessary calls to xTruncate() after committing a transaction. If, ** when a transaction is committed, the dbFileSize variable indicates ** that the database file is larger than the database image (Pager.dbSize), ** pager_truncate() is called. The pager_truncate() call uses xFilesize() ** to measure the database file on disk, and then truncates it if required. ** dbFileSize is not used when rolling back a transaction. In this case ** pager_truncate() is called unconditionally (which means there may be ** a call to xFilesize() that is not strictly required). In either case, ** pager_truncate() may cause the file to become smaller or larger. *** dbHintSize *** The dbHintSize variable is used to limit the number of calls made to ** the VFS xFileControl(FCNTL_SIZE_HINT) method. *** dbHintSize is set to a copy of the dbSize variable when a ** write-transaction is opened (at the same time as dbFileSize and ** dbOrigSize). If the xFileControl(FCNTL_SIZE_HINT) method is called, ** dbHintSize is increased to the number of pages that correspond to the ** size-hint passed to the method call. See pager_write_pagelist() for ** details. *** errCode *** The Pager.errCode variable is only ever used in PAGER_ERROR state. It ** is set to zero in all other states. In PAGER_ERROR state, Pager.errCode ** is always set to SQLITE_FULL, SQLITE_IOERR or one of the SQLITE_IOERR_XXX ** sub-codes.

78323. The left operand

78324. ** When this function is called, *ppPoslist is assumed to point to the ** start of a column-list. After it returns, *ppPoslist points to the ** to the terminator (POS_COLUMN or POS_END) byte of the column-list. *** A column-list is list of delta-encoded positions for a single column ** within a single document within a doclist. *** The column-list is terminated either by a POS_COLUMN varint (1) or ** a POS_END varint (0). This routine leaves *ppPoslist pointing to ** the POS_COLUMN or POS_END that terminates the column-list. *** If pp is not NULL, then the contents of the column-list are copied ** to *pp. *pp is set to point to the first byte past the last byte copied ** before this function returns. The POS_COLUMN or POS_END terminator ** is not copied into *pp.

78325. ** Advance the snippet iterator to the next candidate snippet.

78326. ** Deallocate internal memory used by a WhereLoop object

78327. ** Return the full pathname of the database file. *** Except, if the pager is in-memory only, then return an empty string if ** nullIfMemDb is true. This routine is called with nullIfMemDb==1 when ** used to report the filename to the user, for compatibility with legacy ** behavior. But when the Btree needs to know the

filename for matching to ** shared cache, it uses nullIfMemDb==0 so that in-memory databases can ** participate in shared-cache.

78328. Name context for sub-vdbe

78329. First try to find another RBU vfs lower down in the vfs stack. If ** one is found, this vfs will operate in pass-through mode. The lower ** level vfs will do the special RBU handling.

78330. **comment:** ** The SELECT statement iterating through the keys for the current object ** (p->objiter.pSelect) currently points to a valid row. This function ** determines the type of operation requested by this row and returns ** one of the following values to indicate the result: *** *** * RBU_INSERT *** * RBU_DELETE *** RBU_IDX_DELETE *** RBU_UPDATE *** * If RBU_UPDATE is returned, then output variable *pzMask is set to ** point to the text value indicating the columns to update. *** * If the rbu_control field contains an invalid value, an error code and *** message are left in the RBU handle and zero returned.

label: code-design

78331. **comment:** This routine is never called after sqlite3RowSetNext()

label: requirement

78332. Context that contains this SELECT

78333. Array of WhereLoop objects implementing this path

78334. Register to hold name of table

78335. List of columns to extract.

78336. Bitmask of db->aDb[] entries referenced

78337. ** Delete all information from the single table that pCur is open on. *** * This routine only work for pCur on an ephemeral table.

78338. '+'

78339. Iterates through set of root pages

78340. Values to insert into the %_idx table

78341. Total number of segments

78342. Template WhereLoop under construction

78343. ** An instance of the following structure keeps track of a mapping ** between VDBE cursor numbers and bits of the bitmasks in WhereTerm. *** * The VDBE cursor numbers are small integers contained in ** SrcList_item.iCursor and Expr.iTable fields. For any given WHERE ** clause, the cursor numbers might not begin with 0 and they might ** contain gaps in the numbering sequence. But we want to make maximum ** use of the bits in our bitmasks. This structure provides a mapping ** from the sparse cursor numbers into consecutive integers beginning ** with 0. *** * If WhereMaskSet.ix[A]==B it means that The A-th bit of a Bitmask ** corresponds VDBE cursor number B. The A-th bit of a bitmask is 1<<A. *** * For example, if the WHERE clause expression used these VDBE ** cursors: 4, 5, 8, 29, 57, 73. Then the WhereMaskSet structure ** would map those cursor numbers into bits 0 through 5. *** * Note that the mapping is not necessarily ordered. In the example ** above, the mapping might go like this: 4->3, 5->1, 8->2, 29->0, ** 57->5, 73->4. Or one of 719 other combinations might be used. It ** does not really matter. What is important is that sparse cursor ** numbers all get mapped into bit numbers that begin with 0 and contain ** no gaps.

78344. Type of test to make on this file

78345. ** Like sqlite3ExprCompare() except COLLATE operators at the top-level ** are ignored.

78346. ** 2009 March 3 *** * The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** * May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **

***** This file contains the implementation of the

sqlite3_unlock_notify() ** API method and its associated functionality.

78347. Number of bytes in nKey

78348. ** The sqlite3_mutex_held() and sqlite3_mutex_notheld() routine are ** intended for use only inside assert() statements. On some platforms, ** there might be race conditions that can cause these routines to ** deliver incorrect results. In particular, if pthread_equal() is ** not an atomic operation, then these routines might delivery ** incorrect results. On most platforms, pthread_equal() is a ** comparison of two integers and is therefore atomic. But we are ** told that HPUX is not such a platform. If so, then these routines ** will not always work correctly on HPUX. *** * On those platforms where pthread_equal() is not atomic, SQLite ** should be compiled without -DSQLITE_DEBUG and with -DNDEBUG to ** make sure no assert() statements are evaluated and hence these ** routines are never called.

78349. Number of result rows written here

78350. OUT: Position integer of token

78351. using_opt ::=

78352. The cursor for the index

78353. Original JSON string

78354. ** CAPI3REF: Compare the ages of two snapshot handles. ** EXPERIMENTAL *** * The sqlite3_snapshot_cmp(P1, P2) interface is used to compare the ages ** of two valid snapshot handles. *** * If the two snapshot handles are not associated with the same database ** file, the result of the comparison is undefined. ** Additionally, the result of the comparison is only valid if both of the ** snapshot handles were obtained by calling sqlite3_snapshot_get() since the ** last time the wal file was deleted. The wal file is deleted when the ** database is changed back to rollback mode or when the number of database ** clients drops to zero. If either snapshot handle was obtained before the ** wal file was last deleted, the value returned by this function ** is undefined. *** * Otherwise, this API returns a negative value if P1 refers to an older ** snapshot than P2, zero if the two handles refer to the same database ** snapshot, and a positive value if P1 is a newer snapshot than P2.

78355. Assembled sorter record

78356. ** Apply posix advisory locks for all bytes from ofst through ofst+n-1. *** * Locks block if the mask is exactly UNIX_SHM_C and are non-blocking ** otherwise.

78357. ** Execute the following SQL: *** * DELETE FROM %_data WHERE id BETWEEN \$iFirst AND \$iLast

78358. Increment the nRef value on all name contexts from TopNC up to ** the point where the name matched.

78359. True for "ORDER BY rowid DESC"

78360. Prerequisites of the new entry

78361. Register the result column names for pragmas that return results

78362. **comment:** ** The sqlite3_mutex_alloc() routine allocates a new ** mutex and returns a pointer to it. If it returns NULL ** that means that a mutex could not be allocated. SQLite ** will unwind its stack and return an error. The argument ** to sqlite3_mutex_alloc() is one of these integer constants: *** * ** SQLITE_MUTEX_FAST ** SQLITE_MUTEX_RECURSIVE ** SQLITE_MUTEX_STATIC_MASTER ** SQLITE_MUTEX_STATIC_MEM ** SQLITE_MUTEX_STATIC_OPEN ** SQLITE_MUTEX_STATIC_PRNG ** SQLITE_MUTEX_STATIC_LRU ** SQLITE_MUTEX_STATIC_PMEM ** SQLITE_MUTEX_STATIC_APP1 ** SQLITE_MUTEX_STATIC_APP2 ** SQLITE_MUTEX_STATIC_APP3 ** SQLITE_MUTEX_STATIC_VFS1 ** SQLITE_MUTEX_STATIC_VFS2 ** SQLITE_MUTEX_STATIC_VFS3 ** *** * The first two constants cause sqlite3_mutex_alloc() to create ** a new mutex. The new mutex is recursive when SQLITE_MUTEX_RECURSIVE ** is used but not necessarily so when SQLITE_MUTEX_FAST is used. ** The mutex implementation does not need to make a distinction ** between SQLITE_MUTEX_RECURSIVE and SQLITE_MUTEX_FAST if it does ** not want to. But SQLite will only request a recursive mutex in ** cases where it really needs one. If a faster non-recursive mutex ** implementation is available on the host platform, the mutex subsystem ** might return such a mutex in response to SQLITE_MUTEX_FAST. *** * The other allowed parameters to sqlite3_mutex_alloc() each return ** a pointer to a static preexisting mutex. Six static mutexes are ** used by the current version of SQLite. Future versions of SQLite ** may add additional static mutexes. Static mutexes are for internal ** use by SQLite only. Applications that use SQLite mutexes should ** use only the dynamic mutexes returned by SQLITE_MUTEX_FAST or ** SQLITE_MUTEX_RECURSIVE. *** * Note that if one of the dynamic mutex parameters (SQLITE_MUTEX_FAST ** or SQLITE_MUTEX_RECURSIVE) is used then sqlite3_mutex_alloc() ** returns a different mutex on every call. But for the static ** mutex types, the same mutex is returned on every call that has ** the same type number.

***** This file contains the C functions that implement date and time **
functions for SQLite. ** ** There is only one exported symbol in this file - the function ** sqlite3RegisterDateTimeFunctions() found at the bottom of the file. **
All other code has file scope. ** ** SQLite processes all times and dates as Julian day numbers. The ** dates and times are stored as the number of days since
noon ** in Greenwich on November 24, 4714 B.C. according to the Gregorian ** calendar system. *** 1970-01-01 00:00:00 is JD 2440587.5 ** 2000-01-01
00:00:00 is JD 2451544.5 ** ** This implementation requires years to be expressed as a 4-digit number ** which means that only dates between 0000-01-01 and
9999-12-31 can ** be represented, even though Julian day numbers allow a much wider ** range of dates. ** ** The Gregorian calendar system is used for all
dates and times, ** even those that predate the Gregorian calendar. Historians usually ** use the Julian calendar for dates prior to 1582-10-15 and for some **
dates afterwards, depending on locale. Beware of this difference. ** ** The conversion algorithms are implemented based on descriptions ** in the following text:
*** Jean Meeus ** Astronomical Algorithms, 2nd Edition, 1998 ** ISBN 0-943396-61-1 ** Willmann-Bell, Inc ** Richmond, Virginia (USA)

78727. pagetype

78728. ** Open the shared-memory area associated with database file pDbFd. ** ** When opening a new shared-memory file, if no other instances of that ** file are currently open, in this process or in other processes, then ** the file must be truncated to zero length or have its header cleared.

78729. ** CAPI3REF: Number Of Columns In A Result Set ** METHOD: sqlite3_stmt *** ^Return the number of columns in the result set returned by the ** [prepared statement]. ^If this routine returns 0, that means the ** [prepared statement] returns no data (for example an [UPDATE]). ** ^However, just because this routine returns a positive number does not ** mean that one or more rows of data will be returned. ^A SELECT statement ** will always have a positive sqlite3_column_count() but depending on the ** WHERE clause constraints and the table content, it might return no rows. ** ** See also: [sqlite3_data_count()]

78730. ***** The following three functions, found below: *** ** rbuDeltaGetInt()

** rbuDeltaChecksum() ** rbuDeltaApply() ** ** are lifted from the fossil source code (<http://fossil-scm.org>). They ** are used to implement the scalar SQL function rbu_fossil_delta().

78731. ** Round up a request size to the next valid allocation size. If ** the allocation is too large to be handled by this allocation system, ** return 0. ** ** All allocations must be a power of two and must be expressed by a ** 32-bit signed integer. Hence the largest allocation is 0x40000000 ** or 1073741824 bytes.

78732. Append the prefix-compressed term and doclist to the buffer.

78733. Every page has an associated PCache

78734. EVIDENCE-OF: R-58015-48175 The two-byte integer at offset 5 designates ** the start of the cell content area. A zero value for this integer is ** interpreted as 65536.

78735. 73

78736. Journal omitted.

78737. ** Return the current wal-index header checksum for the target database ** as a 64-bit integer. ** ** The checksum is store in the first page of xShmMap memory as an 8-byte ** blob starting at byte offset 40.

78738. ** Step the RBU object.

78739. ***** Begin file parse.h *****

78740. Initialize the contents of the SnippetIter object. Then iterate through ** the set of phrases in the expression to populate the aPhrase[] array.

78741. Set the output variables and return.

78742. Number of bytes in aRec

78743. A virtual table that is constrained by an IN clause may not ** consume the ORDER BY clause because (1) the order of IN terms ** is not necessarily related to the order of output terms and ** (2) Multiple outputs from a single IN value will not merge ** together.

78744. Mask off the SQLITE_SYNC_* values

78745. ** This routine "expands" a SELECT statement and all of its subqueries. ** For additional information on what it means to "expand" a SELECT ** statement, see the comment on the selectExpand worker callback above. ** ** Expanding a SELECT statement is the first step in processing a ** SELECT statement. The SELECT statement must be expanded before ** name resolution is performed. ** ** If anything goes wrong, an error message is written into pParse. ** The calling function can detect the problem by looking at pParse->nErr ** and/or pParse->db->mallocFailed.

78746. 245

78747. ** Create a new index for an SQL table. pName1.pName2 is the name of the index ** and pTblList is the name of the table that is to be indexed. Both will ** be NULL for a primary key or an index that is created to satisfy a ** UNIQUE constraint. If pTable and pIndex are NULL, use pParse->pNewTable ** as the table to be indexed. pParse->pNewTable is a table that is ** currently being constructed by a CREATE TABLE statement. ** ** pList is a list of columns to be indexed. pList will be NULL if this ** is a primary key or unique-constraint on the most recent column added ** to the table currently under construction.

78748. Set the *pmSeen output variable.

78749. Query the schema of the main database. Create a mirror schema ** in the temporary database.

78750. We are trying for an exclusive lock but another thread in this ** same process is still holding a shared lock.

78751. xUnpin

78752. ** The StrAccum "p" is not large enough to accept N new bytes of z[]. ** So enlarge if first, then do the append. ** ** This is a helper routine to sqlite3StrAccumAppend() that does special-case ** work (enlarging the buffer) using tail recursion, so that the ** sqlite3StrAccumAppend() routine can use fast calling semantics.

78753. CONTINUE and BREAK addresses

78754. Name of the table we are looking for

78755. ***** End of fts3_tokenize_vtab.c *****

78756. Allocate space for the new multi-seg-iterator.

78757. If this is the end of a transaction, then we might need to pad ** the transaction and/or sync the WAL file. ** ** Padding and syncing only occur if this set of frames complete a ** transaction and if PRAGMA synchronous=FULL. If synchronous==NORMAL ** or synchronous==OFF, then no padding or syncing are needed. ** ** If SQLITE_IOCAP_POWERSAFE_OVERWRITE is defined, then padding is not ** needed and only the sync is done. If padding is needed, then the ** final frame is repeated (with its commit mark) until the next sector ** boundary is crossed. Only the part of the WAL prior to the last ** sector boundary is synced; the part of the last frame that extends ** past the sector boundary is written after the sync.

78758. Only allow tracing if SQLITE_DEBUG is defined.

78759. (274) cmdlist ::= ecmd (OPTIMIZED OUT)

78760. Number of buffers currently checked out

78761. Symbolic name of this SELECT use for debugging

78762. Delete a row from an aux. index b-tree

78763. ** Return the number of bytes required to encode v as a varint

78764. Code the SELECTs to our left into temporary table "tab1".

78765. ** 2008 May 26 ** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: ** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. ** ***** This header file is used by programs that want to link against the ** RTREE library. All it does is declare the sqlite3RtreeInit() interface.

78766. Number of bytes of the string text to include in output

78767. **comment:** ** This is called once for each leaf page except the first that contains ** at least one term. Argument (nTerm/pTerm) is the split-key - a term that ** is larger than all terms written to earlier leaves, and equal to or ** smaller than the first term on the new leaf. ** ** If an error occurs, an error code is left in Fts5Index.rc. If an error ** has already occurred when this function is called, it is a no-op.

label: code-design

78768. Buffer to assemble frame-headers in

78769. Reports from the internet are that performance is always ** better if FILE_FLAG_RANDOM_ACCESS is used. Ticket #2699.

78770. The auto-commit flag is true, the vdbe program was successful ** or hit an 'OR FAIL' constraint and there are no deferred foreign ** key constraints to hold up the transaction. This means a commit ** is required.

78771. Cell index within the node

78772. end-if not one-row

78773. ** Each page of the wal-index mapping contains a hash-table made up of ** an array of HASHTABLE_NSLOT elements of the following type.

78774. If the P3 value could not be converted into an integer without ** loss of information, then special processing is required...

78775. Input buffer or stream

78776. Mask of ORDER BY terms that need reversing

78777. EVIDENCE-OF: R-51873-39618 The page size for a database file is ** determined by the 2-byte integer located at an offset of 16 bytes from ** the beginning of the database file.

78778. 9,10,11

78779. First argument for conflict handler

78780. Expression (pLeft != pRight)

78781. If the root node was just loaded, set pRtree->iDepth to the height ** of the r-tree structure. A height of zero means all data is stored on ** the root node. A height of one means the children of the root node ** are the leaves, and so on. If the depth as specified on the root node ** is greater than RTREE_MAX_DEPTH, the r-tree structure must be corrupt.

78782. The x>=y term

78783. Replace with JsonNode.u.iReplace

78784. Address of the OP_IfNot opcode

78785. Minimum local payload in a LEAFDATA table

78786. Create a SrcList structure containing the child table. We need the ** child table as a SrcList for sqlite3WhereBegin()

78787. SQLITE3EXT_H

78788. ** Remove the page supplied as an argument from the hash table ** (PCache1.apHash structure) that it is currently stored in. ** Also free the page if freePage is true. *** The PGroup mutex must be held when this function is called.

78789. Number of UTF-8 characters in zTabName

78790. ** Try to provide a memory barrier operation, needed for initialization ** and also for the implementation of xShmBarrier in the VFS in cases ** where SQLite is compiled without mutexes.

78791. Number of outstanding file locks

78792. Begin a transaction and increment the schema cookie.

78793. ** The following values may be passed as the second argument to ** sqlite3OsLock(). The various locks exhibit the following semantics: *** ** SHARED: Any number of processes may hold a SHARED lock simultaneously. ** RESERVED: A single process may hold a RESERVED lock on a file at ** any time. Other processes may hold and obtain new SHARED locks. ** PENDING: A single process may hold a PENDING lock on a file at ** any one time. Existing SHARED locks may persist, but no new ** SHARED locks may be obtained by other processes. ** EXCLUSIVE: An EXCLUSIVE lock precludes all other locks. *** ** PENDING_LOCK may not be passed directly to sqlite3OsLock(). Instead, a ** process that requests an EXCLUSIVE lock may actually obtain a PENDING ** lock. This can be upgraded to an EXCLUSIVE lock by a subsequent call to ** sqlite3OsLock().

78794. ** Page pParent is an internal (non-leaf) tree page. This function ** asserts that page number iChild is the left-child if the iIdx'th ** cell in page pParent. Or, if iIdx is equal to the total number of ** cells in pParent, that page number iChild is the right-child of ** the page.

78795. Number of aux. indexes on table zTbl

78796. Iterates through aOvfl[]

78797. Figure out if this structure requires optimization. A structure does ** not require optimization if either: *** ** + it consists of fewer than two segments, or ** + all segments are on the same level, or ** + all segments except one are currently inputs to a merge operation. *** ** In the first case, return NULL. In the second, increment the ref-count ** on *pStruct and return a copy of the pointer to it.

78798. ***** Continuing where we left off in sqliteInt.h *****

78799. CURRENT_DATE

78800. **comment:** ** If SQLITE_MALLOC_SOFT_LIMIT is not zero, then try to keep the ** sizes of memory allocations below this value where possible.

label: code-design

78801. **comment:** ** CAPI3REF: Binding Values To Prepared Statements ** KEYWORDS: {host parameter} {host parameters} {host parameter name} ** KEYWORDS: {SQL parameter} {SQL parameters} {parameter binding} ** METHOD: sqlite3_stmt ** ** ^In the SQL statement text input to [sqlite3_prepare_v2()] and its variants, ** literals may be replaced by a [parameter] that matches one of following ** templates: *** ** ** ? ** ? NNN ** :VVV ** @VVV ** \$VVV ** ** ** In the templates above, NNN represents an integer literal, ** and VVV represents an alphanumeric identifier.)** ^The values of these ** parameters (also called "host parameter names" or "SQL parameters") ** can be set using the sqlite3_bind_*() routines defined here. *** ** ^The first argument to the sqlite3_bind_*() routines is always ** a pointer to the [sqlite3_stmt] object returned from ** [sqlite3_prepare_v2()] or its variants. *** ** ^The second argument is the index of the SQL parameter to be set. ** ^The leftmost SQL parameter has an index of 1. ** ^When the same named ** SQL parameter is used more than once, second and subsequent ** occurrences have the same index as the first occurrence. ** ^The index for named parameters can be looked up using the ** [sqlite3_bind_parameter_index()] API if desired. ^The index ** for "?NNN" parameters is the value of NNN. ** ^The NNN value must be between 1 and the [sqlite3_limit()] ** parameter [SQLITE_LIMIT_VARIABLE_NUMBER] (default value: 999). *** ** ^The third argument is the value to bind to the parameter. ** ^If the third parameter to sqlite3_bind_text() or sqlite3_bind_text16() ** or sqlite3_bind_blob() is a NULL pointer then the fourth parameter ** is ignored and the end result is the same as sqlite3_bind_null(). *** ** ^In those routines that have a fourth argument, its value is the ** number of bytes in the parameter. To be clear: the value is the ** number of <u>bytes</u> in the value, not the number of characters.)** ^If the fourth parameter to sqlite3_bind_text() or sqlite3_bind_text16() ** is negative, then the length of the string is ** the number of bytes up to the first zero terminator. ** If the fourth parameter to sqlite3_bind_blob() is negative, then ** the behavior is undefined. ** If a non-negative fourth parameter is provided to sqlite3_bind_text() ** or sqlite3_bind_text16() or sqlite3_bind_text64() then ** that parameter must be the byte offset ** where the NUL terminator would occur assuming the string were NUL ** terminated. If any NUL characters occur at byte offsets less than ** the value of the fourth parameter then the resulting string value will ** contain embedded NULs. The result of expressions involving strings ** with embedded NULs is undefined. *** ** ^The fifth argument to the BLOB and string binding interfaces ** is a destructor used to dispose of the BLOB or ** string after SQLite has finished with it. ^The destructor is called ** to dispose of the BLOB or string even if the call to bind API fails. ** ^If the fifth argument is ** the special value [SQLITE_STATIC], then SQLite assumes that the ** information is in static, unmanaged space and does not need to be freed. ** ^If the fifth argument has the value [SQLITE_TRANSIENT], then ** SQLite makes its own private copy of the data immediately, before ** the sqlite3_bind_*() routine returns. *** ** ^The sixth argument to sqlite3_bind_text64() must be one of ** [SQLITE_UTF8], [SQLITE_UTF16], [SQLITE_UTF16BE], or [SQLITE_UTF16LE] ** to specify the encoding of the text in the third parameter. If ** the sixth argument to sqlite3_bind_text64() is not one of the ** allowed values shown above, or if the text encoding is different ** from the encoding specified by the sixth parameter, then the behavior ** is undefined. *** ** ^The sqlite3_bind_zeroblob() routine binds a BLOB of length N that ** is filled with zeroes. ^A zeroblob uses a fixed amount of memory ** (just an integer to hold its size) while it is being processed. ** Zeroblobs are intended to serve as placeholders for BLOBs whose ** content is later written using ** [sqlite3_blob_open | incremental BLOB I/O] routines. ** ^A negative value for the zeroblob results in a zero-length BLOB. *** ** ^The sqlite3_bind_pointer(S,I,P,T,D) routine causes the I-th parameter in ** [prepared statement] S to have an SQL value of NULL, but to also be ** associated with the pointer P of type T. ^D is either a NULL pointer or ** a pointer to a destructor function for P. ^SQLite will invoke the ** destructor D with a single argument of P when it is finished using ** P. The T parameter should be a static string, preferably a string ** literal. The sqlite3_bind_pointer() routine is part of the ** [pointer passing interface] added for SQLite 3.20.0. *** ** ^If any of the sqlite3_bind_*() routines are called with a NULL pointer ** for the [prepared statement] or with a prepared statement for which ** [sqlite3_step()] has been called more recently than [sqlite3_reset()], ** then the call will return [SQLITE_MISUSE]. If any sqlite3_bind_*() ** routine is passed a [prepared statement] that has been finalized, the ** result is undefined and probably harmful. ** ** ^Bindings are not cleared by the [sqlite3_reset()] routine. ** ^Unbound parameters are interpreted as NULL. *** ** ^The sqlite3_bind_* routines return [SQLITE_OK] on success or an ** [error code] if anything goes wrong. ** ^[SQLITE_TOOBIG] might be returned if the size of a string or BLOB ** exceeds limits imposed by [sqlite3_limit()][SQLITE_LIMIT_LENGTH] or ** [SQLITE_MAX_LENGTH]. ** ^[SQLITE_RANGE] is returned if the parameter ** index is out of range. ^[SQLITE_NOMEM] is returned if malloc() fails. *** ** See also: [sqlite3_bind_parameter_count()], ** [sqlite3_bind_parameter_name()], and [sqlite3_bind_parameter_index()].

78919. ** Open a shared-memory area associated with open database file pDbFd. ** This particular implementation uses mmapped files. *** The file used to implement shared-memory is in the same directory ** as the open database file and has the same name as the open database ** file with the "-shm" suffix added. For example, if the database file ** is "/home/user1/config.db" then the file that is created and mmapped ** for shared memory will be called "/home/user1/config.db-shm". ** ** Another approach to is to use files in /dev/shm or /dev/tmp or an ** some other tmpfs mount. But if a file in a different directory ** from the database file is used, then differing access permissions ** or a chroot() might cause two different processes on the same ** database to end up using different files for shared memory - ** meaning that their memory would not really be shared - resulting ** in database corruption. Nevertheless, this tmpfs file usage ** can be enabled at compile-time using -DSQLITE_SHM_DIRECTORY="/dev/shm" ** or the equivalent. The use of the SQLITE_SHM_DIRECTORY compile-time ** option results in an incompatible build of SQLite; builds of SQLite ** that with differing SQLITE_SHM_DIRECTORY settings attempt to use the ** same database file at the same time, database corruption will likely ** result. The SQLITE_SHM_DIRECTORY compile-time option is considered ** "unsupported" and may go away in a future SQLite release. *** When opening a new shared-memory file, if no other instances of that ** file are currently open, in this process or in other processes, then ** the file must be truncated to zero length or have its header cleared. *** If the original database file (pDbFd) is using the "unix-excl" VFS ** that means that an exclusive lock is held on the database file and ** that no other processes are able to read or write the database. In ** that case, we do not really need shared memory. No shared memory ** file is created. The shared memory will be simulated with heap memory.

79115. SQLITE_MAX_MMAP_SIZE>0
79116. Fts3 cursor for current query
79117. ** Free memory.
79118. Name of the open file
79119. JNODE flags
79120. Pointer to changeset buffer
79121. True if a m-j name has been written to jrn1
79122. Segment to delete
79123. ** CAPI3REF: Flush caches to disk mid-transaction *** ** ^If a write-transaction is open on [database connection] D when the ** [sqlite3_db_cacheflush(D)] interface invoked, any dirty ** pages in the pager-cache that are not currently in use are written out ** to disk. A dirty page may be in use if a database cursor created by an ** active SQL statement is reading from it, or if it is page 1 of a database ** file (page 1 is always "in use"). ^The [sqlite3_db_cacheflush(D)] ** interface flushes caches for all schemas - "main", "temp", and ** any [attached] databases. *** ** ^If this function needs to obtain extra database locks before dirty pages ** can be flushed to disk, it does so. ^If those locks cannot be obtained ** immediately and there is a busy-handler callback configured, it is invoked ** in the usual manner. ^If the required lock still cannot be obtained, then ** the database is skipped and an attempt made to flush any dirty pages ** belonging to the next (if any) database. ^If any databases are skipped ** because locks cannot be obtained, but no other error occurs, this ** function returns SQLITE_BUSY. *** ** ^If any other error occurs while flushing dirty pages to disk (for ** example an IO error or out-of-memory condition), then processing is ** abandoned and an SQLite [error code] is returned to the caller immediately. *** ** ^Otherwise, if no error occurs, [sqlite3_db_cacheflush()] returns SQLITE_OK. *** ** ^This function does not set the database handle error code or message ** returned by the [sqlite3_errcode()] and [sqlite3_errmsg()] functions.
79124. Column number of matching column on the left
79125. SQLITE_CHECKPOINT_* value
79126. ** 2008 Nov 28 *** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** ** May you do good and not evil. **
May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This module contains code that implements a parser for
fts3 query strings ** (the right-hand argument to the MATCH operator). Because the supported ** syntax is relatively simple, the whole tokenizer/parser system is
** hand-coded.
79127. 0 = main program, 1 = first sub-program etc.
79128. True when aMatchinfo[] needs filling in
79129. Open file descriptor
79130. Error code from db file unlock operation
79131. ** Examine a WherePath (with the addition of the extra WhereLoop of the 6th ** parameters) to see if it outputs rows in the requested ORDER BY ** (or GROUP BY) without requiring a separate sort operation. Return N: ** ** N>0: N terms of the ORDER BY clause are satisfied ** N==0: No terms of the ORDER BY clause are satisfied ** N<0: Unknown yet how many terms of ORDER BY might be satisfied. *** ** Note that processing for WHERE_GROUPBY and WHERE_DISTINCTBY is not as ** strict. With GROUP BY and DISTINCT the only requirement is that ** equivalent rows appear immediately adjacent to one another. GROUP BY ** and DISTINCT do not require rows to appear in any particular order as long ** as equivalent rows are grouped together. Thus for GROUP BY and DISTINCT ** the pOrderBy terms can be matched in any order. With ORDER BY, the ** pOrderBy terms must be matched in strict left-to-right order.
79132. ** Copy the contents of object (*pFrom) into (*pTo).
79133. Opcode: SeekLT P1 P2 P3 P4 * ** Synopsis: key=r[P3@P4] ** ** If cursor P1 refers to an SQL table (B-Tree that uses integer keys), ** use the value in register P3 as a key. If cursor P1 refers ** to an SQL index, then P3 is the first in an array of P4 registers ** that are used as an unpacked index key. *** ** Reposition cursor P1 so that it points to the largest entry that ** is less than the key value. If there are no records less than ** the key and P2 is not zero, then jump to P2. **
** This opcode leaves the cursor configured to move in reverse order, ** from the end toward the beginning. In other words, the cursor is ** configured to use Prev, not Next. ** ** See also: Found, NotFound, SeekGt, SeekGe, SeekLe
79134. Before doing anything else, call the xSync() callback for any ** virtual module tables written in this transaction. This has to ** be done before determining whether a master journal file is ** required, as an xSync() callback may add an attached database ** to the transaction.
79135. Result from sqlite3Reprepare()
79136. Index.aiRowEst may already be set here if there are duplicate ** sqlite_stat1 entries for this index. In that case just clobber ** the old data with the new instead of allocating a new array.
79137. ** The parser calls this routine in order to create a new VIEW
79138. Parent table of foreign key pFKey
79139. (324) vtabarglist ::= vtabarglist COMMA vtabarg
79140. ** Instances of this structure are used to build strings or binary records.
79141. Opcode: MakeRecord P1 P2 P3 P4 * ** Synopsis: r[P3]=mkrec(r[P1@P2]) ** ** Convert P2 registers beginning with P1 into the [record format] ** use as a data record in a database table or as a key ** in an index. The OP_Column opcode can decode the record later. *** ** P4 may be a string that is P2 characters long. The N-th character of the ** string indicates the column affinity that should be used for the N-th ** field of the index key. *** ** The mapping from character to affinity is given by the SQLITE_AFF_ ** macros defined in sqliteInt.h. *** ** If P4 is NULL then all index fields have the affinity BLOB.
79142. SELECTTRACE_ENABLED
79143. Number of pages in the database according to hdr
79144. Insert an implicit AND operator.
79145. ***** Begin file mutex_noop.c *****
79146. ON DELETE and ON UPDATE actions, respectively
79147. same as TK_LE, jump, in1, in3
79148. Docid to read size data for
79149. ifndef SQLITE OMIT_AUTOVACUUM
79150. (term <= \$zLeTerm) paramater, or NULL
79151. How to dispose of the results
79152. synopsis: r[P2]=P4
79153. Number of pages in pList
79154. Table structure

79155. The main DB, main journal, WAL file and master journal are never ** automatically deleted. Nor are they ever temporary files.
79156. Size of term suffix in bytes
79157. Adjust downward, as appropriate
79158. OUT: Bytes stored locally
79159. If this instruction implements a COMMIT and other VMs are writing ** return an error indicating that the other VMs must complete first.
79160. Parsing contexts
79161. Type of the RHS
79162. Cursor open on pIdx
79163. ** PRAGMA wal_autocheckpoint ** PRAGMA wal_autocheckpoint = N ** ** Configure a database connection to automatically checkpoint a database ** after accumulating N frames in the log. Or query for the current value ** of N.
79164. FTS3 table cursor
79165. Number of columns in the result set
79166. ** sqlite3_test_control(SQLITE_TESTCTRL_PENDING_BYTE, unsigned int X) ** ** Set the PENDING byte to the value in the argument, if X>0. ** Make no changes if X==0. Return the value of the pending byte ** as it existing before this routine was called. ** ** IMPORTANT: Changing the PENDING byte from 0x40000000 results in ** an incompatible database file format. Changing the PENDING byte ** while any database connection is open results in undefined and ** deleterious behavior.
79167. Used to iterate through zArg
79168. One-time setup cost (ex: create transient index)
79169. If an EXCLUSIVE lock can be obtained on the database file (using the ** ordinary, rollback-mode locking methods, this guarantees that the ** connection associated with this log file is the only connection to ** the database. In this case checkpoint the database and unlink both ** the wal and wal-index files. ** ** The EXCLUSIVE lock is not released before returning.
79170. **comment:** Clean up before exiting
label: code-design
79171. ** This is the xFilter implementation for the virtual table.
79172. Collision detection may be omitted if all of the following are true: ** (1) The conflict resolution algorithm is REPLACE ** (2) The table is a WITHOUT ROWID table ** (3) There are no secondary indexes on the table ** (4) No delete triggers need to be fired if there is a conflict ** (5) No FK constraint counters need to be updated if a conflict occurs.
79173. Pointer to buffer containing changeset B
79174. Register containing index name
79175. 440
79176. ** Internal types used by SQLite.
79177. Number of trailing arguments for rank()
79178. Number of entries currently in hash
79179. **comment:** ** Growing our own isspace() routine this way is twice as fast as ** the library isspace() function, resulting in a 7% overall performance ** increase for the parser. (Ubuntu14.10 gcc 4.8.4 x64 with -Os).
label: code-design
79180. **comment:** ** Close a file descriptor. ** ** We assume that close() almost always works, since it is only in a ** very sick application or on a very sick platform that it might fail. ** If it does fail, simply leak the file descriptor, but do log the ** error. ** ** Note that it is not safe to retry close() after EINTR since the ** file descriptor might have already been reused by another thread. ** So we don't even try to recover from an EINTR. Just log the error ** and move on.
label: code-design
79181. Flags this file descriptor was opened with
79182. ** The makefile scans the vdbe.c source file and creates the "opcodes.h" ** header file that defines a number for each opcode used by the VDBE.
79183. flags = BTREE_INTKEY;
79184. ** Parameters z and n contain a pointer to and length of a buffer containing ** an fts3 query expression, respectively. This function attempts to parse the ** query expression and create a tree of Fts3Expr structures representing the ** parsed expression. If successful, *ppExpr is set to point to the head ** of the parsed expression tree and SQLITE_OK is returned. If an error ** occurs, either SQLITE_NOMEM (out-of-memory error) or SQLITE_ERROR (parse ** error) is returned and *ppExpr is set to 0. ** ** If parameter n is a negative number, then z is assumed to point to a ** nul-terminated string and the length is determined using strlen(). ** ** The first parameter, pTokenizer, is passed the fts3 tokenizer module to ** use to normalize query tokens while parsing the expression. The azCol[] ** array, which is assumed to contain nCol entries, should contain the names ** of each column in the target fts3 table, in order from left to right. ** Column names must be nul-terminated strings. ** ** The iDefaultCol parameter should be passed the index of the table column ** that appears on the left-hand-side of the MATCH operator (the default ** column to match against for tokens for which a column name is not explicitly ** specified as part of the query string), or -1 if tokens may by default ** match any table column.
79185. Set iRoot to the index in pWriter->aNodeWriter[] of the output segment ** root node. If the segment fits entirely on a single leaf node, iRoot ** will be set to 0. If the root node is the parent of the leaves, iRoot ** will be 1. And so on.

If the ** value in register P3 is not NULL, then this routine is a no-op. ** The P5 parameter should be 1.

79305. Current index for apPage[iPage]

79306. Continue rolling back records out of the main journal starting at ** the first journal header seen and continuing until the effective end ** of the main journal file. Continue to skip out-of-range pages and ** continue adding pages rolled back to pDone.

79307. This virtual table always delivers results in ascending order of ** the "term" column (column 0). So if the user has requested this ** specifically - "ORDER BY term" or "ORDER BY term ASC" - set the ** sqlite3_index_info.orderByConsumed flag to tell the core the results ** are already in sorted order.

79308. Comparing signed and unsigned

79309. ** Generate code for a boolean expression such that a jump is made ** to the label "dest" if the expression is false but execution ** continues straight thru if the expression is true. *** If the expression evaluates to NULL (neither true nor false) then ** jump if jumpIfNull is SQLITE_JUMPIFNULL or fall through if jumpIfNull ** is 0.

79310. ** Register all built-in tokenizers with FTS5.

79311. If a journal file exists, and there is no RESERVED lock on the ** database file, then it either needs to be played back or deleted.

79312. Bytes of space to allocate

79313. sqlite3_create_collation only

79314. Document being tokenized

79315. Unless i==Idx->nSample, indicating that pRec is larger than ** all samples in the aSample[] array, pRec must be smaller than the ** (iCol+1) field prefix of sample i.

79316. ** Maximum depth of recursion for triggers. *** A value of 1 means that a trigger program will not be able to itself ** fire any triggers. A value of 0 means that no trigger programs at all ** may be executed.

79317. Code an OP_Transaction and OP_TableLock for <table>.

79318. ** Call sqlite3WalkExpr() for every expression in Select statement p. ** Invoke sqlite3WalkSelect() for subqueries in the FROM clause and ** on the compound select chain, p->pPrior. *** If it is not NULL, the xSelectCallback() callback is invoked before ** the walk of the expressions and FROM clause. The xSelectCallback2() ** method is invoked following the walk of the expressions and FROM clause, ** but only if both xSelectCallback and xSelectCallback2 are both non-NULL ** and if the expressions and FROM clause both return WRC_Continue; ** ** Return WRC_Continue under normal conditions. Return WRC_Abort if ** there is an abort request. *** If the Walker does not have an xSelectCallback() then this routine ** is a no-op returning WRC_Continue.

79319. Return code from subroutines

79320. If pPrior is part of the data area of pPage, then make sure pPage ** is still writeable

79321. Path to this page

79322. If an expression is an integer literal that fits in a signed 32-bit ** integer, then the EP_IntValue flag will have already been set

79323. Used for rounding floating point values

79324. ** Return information regarding the PRIMARY KEY and number of columns in ** the database table affected by the change that pIter currently points ** to. This function may only be called after changeset_next() returns ** SQLITE_ROW.

79325. Trigger Name Table Name

79326. ** These macros can be used to test, set, or clear bits in the ** Db.pSchema->flags field.

79327. Call the progress callback if it is configured and the required number ** of VDBE ops have been executed (either since this invocation of ** sqlite3VdbeExec() or since last time the progress callback was called). ** If the progress callback returns non-zero, exit the virtual machine with ** a return code SQLITE_ABORT.

79328. 178
79329. Vdbe to add code to
79330. "nlt" column of stat[34] entry
79331. ** pEList is the SET clause of an UPDATE statement. Each entry ** in pEList is of the format <id>=<expr>. If any of the entries ** in pEList have an <id> which matches an identifier in pIdList, ** then return TRUE. If pIdList==NULL, then it is considered a ** wildcard that matches anything. Likewise if pEList==NULL then ** it matches anything so always return true. Return false only ** if there is no match.
79332. ** Create an iterator used to iterate through the contents of a changeset.
79333. Open the target, RBU and state databases
79334. ***** Begin file prepare.c *****
79335. Built-in affinity() function
79336. The longest decimal representation of a 32 bit integer is 10 digits: ** ** 1234567890 ** 2^31 -> 2147483648
79337. page-size bytes of space for parent ovfl
79338. Parent table of FK pFKey
79339. Rowid of last value written
79340. All (named) indices indexed by name
79341. **comment:** ** A call to this routine tells the pager that it is not necessary to ** write the information on page pPg back to the disk, even though ** that page might be marked as dirty. This happens, for example, when ** the page has been added as a leaf of the freelist and so its ** content no longer matters. ** ** The overlying software layer calls this routine when all of the data ** on the given page is unused. The pager marks the page as clean so ** that it does not get written to disk. ** ** Tests show that this optimization can quadruple the speed of large ** DELETE operations. ** ** This optimization cannot be used with a temp-file, as the page may ** have been dirty at the start of the transaction. In that case, if ** memory pressure forces page pPg out of the cache, the data does need ** to be written out to disk so that it may be read back in if the ** current transaction is rolled back.
label: code-design
79342. ***** End of vdbe.c *****
79343. ** CAPI3REF: Collation Needed Callbacks ** METHOD: sqlite3 *** ^To avoid having to register all collation sequences before a database ** can be used, a single callback function may be registered with the ** [database connection] to be invoked whenever an undefined collation ** sequence is required. ** ** ^If the function is registered using the sqlite3_collation_needed() API, ** then it is passed the names of undefined collation sequences as strings ** encoded in UTF-8. ^If sqlite3_collation_needed16() is used, ** the names are passed as UTF-16 in machine native byte order. ** ^A call to either function replaces the existing collation-needed callback. ** ** ^When the callback is invoked, the first argument passed is a copy ** of the second argument to sqlite3_collation_needed() or ** sqlite3_collation_needed16(). The second argument is the database ** connection. The third argument is one of [SQLITE_UTF8], [SQLITE_UTF16BE], ** or [SQLITE_UTF16LE], indicating the most desirable form of the collation ** sequence function required. The fourth parameter is the name of the ** required collation sequence.)^ ** ** The callback function should register the desired collation using ** [sqlite3_create_collation()], [sqlite3_create_collation16()], or ** [sqlite3_create_collation_v2()].

May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **

***** This file contains code associated with the ANALYZE command.

*** The ANALYZE command gather statistics about the content of tables ** and indices. These statistics are made available to the query planner ** to help it
make better decisions about how to perform queries. *** The following system tables are or have been supported: *** CREATE TABLE sqlite_stat1(tbl, idx,
stat); ** CREATE TABLE sqlite_stat2(tbl, idx, samplen, sample); ** CREATE TABLE sqlite_stat3(tbl, idx, nEq, nLt, nDLt, sample); ** CREATE TABLE
sqlite_stat4(tbl, idx, nEq, nLt, nDLt, sample); *** Additional tables might be added in future releases of SQLite. ** The sqlite_stat2 table is not created or used
unless the SQLite version ** is between 3.6.18 and 3.7.8, inclusive, and unless SQLite is compiled ** with SQLITE_ENABLE_STAT2. The sqlite_stat2 table is
deprecated. ** The sqlite_stat2 table is superseded by sqlite_stat3, which is only ** created and used by SQLite versions 3.7.9 and later and with **

SQLITE_ENABLE_STAT3 defined. The functionality of sqlite_stat3 ** is a superset of sqlite_stat2. The sqlite_stat4 is an enhanced ** version of sqlite_stat3 and
is only available when compiled with ** SQLITE_ENABLE_STAT4 and in SQLite versions 3.8.1 and later. It is ** not possible to enable both STAT3 and STAT4
at the same time. If they ** are both enabled, then STAT4 takes precedence. *** For most applications, sqlite_stat1 provides all the statistics required ** for the
query planner to make good choices. *** Format of sqlite_stat1: *** There is normally one row per index, with the index identified by the ** name in the idx
column. The tbl column is the name of the table to ** which the index belongs. In each such row, the stat column will be ** a string consisting of a list of integers.
The first integer in this ** list is the number of rows in the index. (This is the same as the ** number of rows in the table, except for partial indices.) The second **
integer is the average number of rows in the index that have the same ** value in the first column of the index. The third integer is the average ** number of rows
in the index that have the same value for the first two ** columns. The N-th integer (for N>1) is the average number of rows in ** the index which have the same
value for the first N-1 columns. For ** a K-column index, there will be K+1 integers in the stat column. If ** the index is unique, then the last integer will be 1. **

** The list of integers in the stat column can optionally be followed ** by the keyword "unordered". The "unordered" keyword, if it is present, ** must be separated from the last integer by a single space. If the ** "unordered" keyword is present, then the query planner assumes that ** the index is unordered and will not use the index for a range query. *** If the sqlite_stat1.idx column is NULL, then the sqlite_stat1.stat ** column contains a single integer which is the (estimated) number of ** rows in the table identified by sqlite_stat1.tbl. *** Format of sqlite_stat2: *** The sqlite_stat2 is only created and is only used if SQLite is compiled ** with SQLITE_ENABLE_STAT2 and if the SQLite version number is between ** 3.6.18 and 3.7.8. The "stat2" table contains additional information ** about the distribution of keys within an index. The index is identified by ** the "idx" column and the "tbl" column is the name of the table to which ** the index belongs. There are usually 10 rows in the sqlite_stat2 ** table for each index. *** The sqlite_stat2 entries for an index that have samples between 0 and 9 ** inclusive are samples of the left-most key value in the index taken at ** evenly spaced points along the index. Let the number of samples be S ** (10 in the standard build) and let C be the number of rows in the index. ** Then the sampled rows are given by: *** rownumber = (i*C*2 + C)/(S*2) *** For i between 0 and S-1. Conceptually, the index space is divided into ** S uniform buckets and the samples are the middle row from each bucket. *** The format for sqlite_stat2 is recorded here for legacy reference. This ** version of SQLite does not support sqlite_stat2. It neither reads nor ** writes the sqlite_stat2 table. This version of SQLite only supports ** sqlite_stat3. *** Format for sqlite_stat3: *** The sqlite_stat3 format is a subset of sqlite_stat4. Hence, the ** sqlite_stat4 format will be described first. Further information ** about sqlite_stat3 follows the sqlite_stat4 description. *** Format for sqlite_stat4: *** As with sqlite_stat2, the sqlite_stat4 table contains histogram data ** to aid the query planner in choosing good indices based on the values ** that indexed columns are compared against in the WHERE clauses of ** queries. *** The sqlite_stat4 table contains multiple entries for each index. ** The idx column names the index and the tbl column is the table of the ** index. If the idx and tbl columns are the same, then the sample is ** of the INTEGER PRIMARY KEY. The sample column is a blob which is the ** binary encoding of a key from the index. The nEq column is a ** list of integers. The first integer is the approximate number ** of entries in the index whose left-most column exactly matches ** the left-most column of the sample. The second integer in nEq ** is the approximate number of entries in the index where the ** first two columns match the first two columns of the sample. ** And so forth. nLt is another list of integers that show the approximate ** number of entries that are strictly less than the sample. The first ** integer in nLt contains the number of entries in the index where the ** left-most column is less than the left-most column of the sample. ** The K-th integer in the nLt entry is the number of index entries ** where the first K columns are less than the first K columns of the ** sample. The nDLt column is like nLt except that it contains the ** number of distinct entries in the index that are less than the ** sample. *** There can be an arbitrary number of sqlite_stat4 entries per index. ** The ANALYZE command will typically generate sqlite_stat4 tables ** that contain between 10 and 40 samples which are distributed across ** the key space, though not uniformly, and which include samples with ** large nEq values. *** Format for sqlite_stat3 redux: *** The sqlite_stat3 table is like sqlite_stat4 except that it only ** looks at the left-most column of the index. The sqlite_stat3.sample ** column contains the actual value of the left-most column instead ** of a blob encoding of the complete index key as is found in ** sqlite_stat4.sample. The nEq, nLt, and nDLt entries of sqlite_stat3 ** all contain just a single integer which is the same as the first ** integer in the equivalent columns in sqlite_stat4.

79815. Minimum PMA size, in bytes

79816. ** Append a string to the string-buffer passed as the first argument. *** If nAppend is negative, then the length of the string zAppend is ** determined using strlen().

79817. Tracing routines for the RtreeSearchPoint queue

79818. Turn bulk memory into a hash table object by initializing the ** fields of the Hash structure. *** "pNew" is a pointer to the hash table that is to be initialized. ** keyClass is one of the constants ** FTS3_HASH_BINARY or FTS3_HASH_STRING. The value of keyClass ** determines what kind of key the hash table will use. "copyKey" is ** true if the hash table should make its own private copy of keys and ** false if it should just use the supplied pointer.

79819. Version 3.7.16 and later

79820. ** Delete an entire expression list.

79821. expr ::= NOT expr

79822. ** The input to this routine is an WhereTerm structure with only the ** "pExpr" field filled in. The job of this routine is to analyze the ** subexpression and populate all the other fields of the WhereTerm ** structure. *** If the expression is of the form "<expr> <op> X" it gets commuted ** to the standard form of "X <op> <expr>". *** If the expression is of the form "X <op> Y" where both X and Y are ** columns, then the original expression is unchanged and a new virtual ** term of the form "Y <op> X" is added to the WHERE clause and ** analyzed separately. The original term is marked with TERM_COPIED ** and the new term is marked with TERM_DYNAMIC (because it's pExpr ** needs to be freed with the WhereClause) and TERM_VIRTUAL (because it ** is a commuted copy of a prior term.) The original term has nChild=1 ** and the copy has idxParent set to the index of the original term.

79823. The transaction counter has changed

79824. Array of column names

79825. ** A structure defining how to do GLOB-style comparisons.

79826. ** Move the cursor down to the right-most leaf entry beneath the ** page to which it is currently pointing. Notice the difference ** between moveToLeftmost() and moveToRightmost(). moveToLeftmost() ** finds the left-most entry beneath the *entry* whereas moveToRightmost() ** finds the right-most entry beneath the *page*. *** The right-most entry is the one with the largest key - the last ** key in ascending order.

79865. ** CAPI3REF: Virtual Table Constraint Operator Codes *** ** These macros defined the allowed values for the ** [sqlite3_index_info].aConstraint[].op field. Each value represents ** an operator that is part of a constraint term in the WHERE clause of ** a query that uses a [virtual table].

79866. ** This is the xSetSystemCall() method of sqlite3_vfs for all of the ** "win32" VFSes. Return SQLITE_OK upon successfully updating the ** system call pointer, or SQLITE_NOTFOUND if there is no configurable ** system call named zName.

79867. No additional checks needed for this table

79868. Starting offset in main journal

79869. Locate the pragma in the lookup table

79870. Any terms specified as part of the ON(...) clause for any LEFT ** JOIN for which the current table is not the rhs are omitted ** from the cursor-hint. *** ** If this table is the rhs of a LEFT JOIN, "IS" or "IS NULL" terms ** that were specified as part of the WHERE clause must be excluded. ** This is to address the following: ** ** SELECT ... t1 LEFT JOIN t2 ON (t1.a=t2.b) WHERE t2.c IS NULL; ** ** Say there is a single row in t2 that matches (t1.a=t2.b), but its ** t2.c values is not NULL. If the (t2.c IS NULL) constraint is ** pushed down to the cursor, this row is filtered out, causing ** SQLite to synthesize a row of NULL values. Which does match the ** WHERE clause, and so the query returns a row. Which is incorrect. *** ** For the same reason, WHERE terms such as: *** ** WHERE 1 = (t2.c IS NULL) *** are also excluded. See codeCursorHintIsOrFunction() for details.

79871. Space used in zNewRecord[] content

79872. ** 2003 April 6 *** ** The author disclaims copyright to this source code. In place of ** a legal notice, here is a blessing: *** ** May you do good and not evil. ** May you find forgiveness for yourself and forgive others. ** May you share freely, never taking more than you give. **
***** This file contains code used to implement the ATTACH and DETACH commands.

79873. ** Remove node pNode from the node hash table.

79874. Value passed to FCNTL_SIZE_HINT call

79875. ** One or more segments have just been removed from absolute level iAbsLevel. ** Update the 'idx' values of the remaining segments in the level so that ** the idx values are a contiguous sequence starting from 0.

79876. ** Carve a piece off of the end of the mem3.iMaster free chunk. ** Return a pointer to the new allocation. Or, if the master chunk ** is not large enough, return 0.

79877. Verify condition (1): If cells are moving left, update iPg ** only after iPg-1 has already been updated.

79878. ** Initialize the object pItr to point to term pTerm/nTerm within segment ** pSeg. If there is no such term in the index, the iterator is set to EOF. *** ** If an error occurs, Fts5Index.rc is set to an appropriate error code. If ** an error has already occurred when this function is called, it is a no-op.

79879. 0: off 1: simple 2: cache dumps

79880. Page into which we are copying

79881. ** Query status information for a single database connection

79882. List of all WhereLoop objects

79883. ** An instance of the following structure serves as the key used ** to locate a particular unixInodeInfo object.

79884. ** Add all WhereLoop objects for a table of the join identified by ** pBuilder->pNew->iTab. That table is guaranteed to be a virtual table. *** ** If there are no LEFT or CROSS JOIN joins in the query, both mPrereq and ** mUnusable are set to 0. Otherwise, mPrereq is a mask of all FROM clause ** entries that occur before the virtual table in the FROM clause and are ** separated from it by at least one LEFT or CROSS JOIN. Similarly, the ** mUnusable mask contains all FROM clause entries that occur after the ** virtual table and are separated from it by at least one LEFT or ** CROSS JOIN. *** ** For example, if the query were: *** ... FROM t1, t2 LEFT JOIN t3, t4, vt CROSS JOIN t5, t6; ** ** then mPrereq corresponds to (t1, t2) and mUnusable to (t5, t6). *** ** All the tables in mPrereq must be scanned before the current virtual ** table. So any terms for which all prerequisites are satisfied by ** mPrereq may be specified as "usable" in all calls to xBestIndex. ** Conversely, all tables in mUnusable must be scanned after the current ** virtual table, so any terms for which the prerequisites overlap with ** mUnusable should always be configured as "not-usable" for xBestIndex.

79885. API oddity: If successful, SetFilePointer() returns a dword ** containing the lower 32-bits of the new file-offset. Or, if it fails, ** it returns INVALID_SET_FILE_POINTER. However according to MSDN, ** INVALID_SET_FILE_POINTER may also be a valid new offset. So to determine ** whether an error has actually occurred, it is also necessary to call ** GetLastError().

79886. True if a leaf page

79887. ** CAPI3REF: Error Logging Interface *** ** ^The [sqlite3_log0] interface writes a message into the [error log] ** established by the [SQLITE_CONFIG_LOG] option to [sqlite3_config0]. ** ^If logging is enabled, the zFormat string and subsequent arguments are ** used with [sqlite3_snprintf0] to generate the final output string. *** ** The sqlite3_log0 interface is intended for use by extensions such as ** virtual tables, collating functions, and SQL functions. While there is ** nothing to prevent an application from calling sqlite3_log0, doing so ** is considered bad form. *** ** The zFormat string must not be NULL. *** ** To avoid deadlocks and other threading problems, the sqlite3_log0 routine ** will not use dynamically allocated memory. The log message is stored in ** a fixed-length buffer on the stack. If the log message is longer than ** a few hundred characters, it will be truncated to the length of the ** buffer.

79888. Add number of Cells freed to this counter

79889. ** Begin a write-transaction on the specified pager object. If a ** write-transaction has already been opened, this function is a no-op. *** ** If the exFlag argument is false, then acquire at least a RESERVED ** lock on the database file. If exFlag is true, then acquire at least ** an EXCLUSIVE lock. If such a lock is already held, no locking ** functions need be called. *** ** If the subjInMemory argument is non-zero, then any sub-journal opened ** within this transaction will be opened as an in-memory file. This ** has no effect if the sub-journal is already opened (as it may be when ** running in exclusive mode) or if the transaction does not require a ** sub-journal. If the subjInMemory argument is zero, then any required ** sub-journal is implemented in-memory if pPager is an in-memory database, ** or using a temporary file otherwise.

label: code-design
79907. ** This function is used to estimate the number of rows that will be visited ** by scanning an index for a range of values. The range may have an upper ** bound, a lower bound, or both. The WHERE clause terms that set the upper ** and lower bounds are represented by pLower and pUpper respectively. For ** example, assuming that index p is on t1(a): ** ** ... FROM t1 WHERE a > ? AND a < ? ... ** |_____|_____|** || ** pLower pUpper ** ** If either of the upper or lower bound is not present, then NULL is passed in ** place of the corresponding WhereTerm. ** ** The value in (pBuilder->pNew->u.btree.nEq) is the number of the index ** column subject to the range constraint. Or, equivalently, the number of ** equality constraints optimized by the proposed index scan. For example, ** assuming index p is on t1(a, b), and the SQL query is: ** ** ... FROM t1 WHERE a = ? AND b > ? AND b < ? ... ** ** then nEq is set to 1 (as the range restricted column, b, is the second ** left-most column of the index). Or, if the query is: ** ** ... FROM t1 WHERE a > ? AND a < ? ... ** ** then nEq is set to 0. ** ** When this function is called, *pnOut is set to the sqlite3LogEst() of the ** number of rows that the index scan is expected to visit without ** considering the range constraints. If nEq is 0, then *pnOut is the number of ** rows in the index. Assuming no error occurs, *pnOut is adjusted (reduced) ** to account for the range constraints pLower and pUpper. ** ** In the absence of sqlite_stat4 ANALYZE data, or if such data cannot be ** used, a single range inequality reduces the search space by a factor of 4. ** and a pair of constraints (x>? AND x<?) reduces the expected number of ** rows visited by a factor of 64.
79908. ** Each node of an expression in the parse tree is an instance ** of this structure. ** ** Expr.op is the opcode. The integer parser token codes are reused ** as opcodes here. For example, the parser defines TK_GE to be an integer ** code representing the ">=" operator. This same integer code is reused ** to represent the greater-than-or-equal-to operator in the expression ** tree. ** ** If the expression is an SQL literal (TK_INTEGER, TK_FLOAT, TK_BLOB, ** or TK_STRING), then Expr.token contains the text of the SQL literal. If ** the expression is a variable (TK_VARIABLE), then Expr.token contains the ** variable name. Finally, if the expression is an SQL function (TK_FUNCTION), ** then Expr.token contains the name of the function. ** ** Expr.pRight and Expr.pLeft are the left and right subexpressions of a ** binary operator. Either or both may be NULL. ** ** Expr.x.pList is a list of arguments if the expression is an SQL function, ** a CASE expression or an IN expression of the form "<lhs> IN (<y>, <z>)". ** Expr.x.pSelect is used if the expression is a sub-select or an expression of ** the form "<lhs> IN (SELECT ...)". If the EP_XIsSelect bit is set in the ** Expr.flags mask, then Expr.x.pSelect is valid. Otherwise, Expr.x.pList is ** valid. ** ** An expression of the form ID or ID.ID refers to a column in a table. ** For such expressions, Expr.op is set to TK_COLUMN and Expr.iTable is ** the integer cursor number of a VDBE cursor pointing to that table and ** Expr.iColumn is the column number for the specific column. If the ** expression is used as a result in an aggregate SELECT, then the ** value is also stored in the Expr.iAgg column in the aggregate so that ** it can be accessed after all aggregates are computed. ** ** If the expression is an unbound variable marker (a question mark ** character '?' in the original SQL) then the Expr.iTable holds the index ** number for that variable. ** ** If the expression is a subquery then Expr.iColumn holds an integer ** register number containing the result of the subquery. If the ** subquery gives a constant result, then iTable is -1. If the subquery ** gives a different answer at different times during statement processing ** then iTable is the address of a subroutine that computes the subquery. ** ** If the Expr is of type OP_Column, and the table it is selecting from ** is a disk table or the "old."** pseudo-table, then pTab points to the ** corresponding table definition. ** ** ALLOCATION NOTES: ** ** Expr objects can use a lot of memory space in database schema. To ** help reduce memory requirements, sometimes an Expr object will be ** truncated. And to reduce the number of memory allocations, sometimes ** two or more Expr objects will be stored in a single memory allocation, ** together with Expr.zToken strings. ** ** If the EP_Reduced and EP_TokenOnly flags are set when ** an Expr object is truncated. When EP_Reduced is set, then all ** the child Expr objects in the Expr.pLeft and Expr.pRight subtrees ** are contained within the same memory allocation. Note, however, that ** the subtrees in Expr.x.pList or Expr.x.pSelect are always separately ** allocated, regardless of whether or not EP_Reduced is set.

79989. **comment:** ** CAPI3REF: Streaming Versions of API functions. *** The six streaming API xxx_strm() functions serve similar purposes to the ** corresponding non-streaming API functions: *** <table border=1 style="margin-left:8ex;margin-right:8ex"> ** <tr><th>Streaming function</th><th>Non-streaming equivalent</th> ** <tr><td>sqlite3changeset_apply_str<td>[sqlite3changeset_apply] ** <tr><td>sqlite3changeset_concat_str<td>[sqlite3changeset_concat] ** <tr><td>sqlite3changeset_invert_str<td>[sqlite3changeset_invert] ** <tr><td>sqlite3changeset_start_str<td>[sqlite3changeset_start] ** <tr><td>sqlite3session_changeset_str<td>[sqlite3session_changeset] ** <tr><td>sqlite3session_patchset_str<td>[sqlite3session_patchset] ** </table> *** Non-streaming functions that accept changesets (or patchsets) as input ** require that the entire changeset be stored in a single buffer in memory. ** Similarly, those that return a changeset or patchset do so by returning ** a pointer to a single large buffer allocated using sqlite3_malloc(). ** Normally this is convenient. However, if an application running in a ** low-memory environment is required to handle very large changesets, the ** large contiguous memory allocations required can become onerous. ** In order to avoid this problem, instead of a single large buffer, input ** is passed to a streaming API functions by way of a callback function that ** the sessions module invokes to incrementally request input data as it is ** required. In all cases, a pair of API function parameters such as *** <pre> ** &nbs; int nChangeset, ** &nbs; void *pChangeset, ** </pre> *** Is replaced by: *** <pre> ** &nbs; int (*xInput)(void *pIn, void *pData, int *nData), ** &nbs; void *pIn, ** </pre> *** Each time the xInput callback is invoked by the sessions module, the first ** argument passed is a copy of the supplied pIn context pointer. The second ** argument, pData, points to a buffer (*nData) bytes in size. Assuming no ** error occurs the xInput method should copy up to (*nData) bytes of data ** into the buffer and set (*nData) to the actual number of bytes copied ** before returning SQLITE_OK. If the input is completely exhausted, (*nData) ** should be set to zero to indicate this. Or, if an error occurs, an SQLite ** error code should be returned. In all cases, if an xInput callback returns ** an error, all processing is abandoned and the streaming API function ** returns a copy of the error code to the caller. *** In the case of sqlite3changeset_start_strm(), the xInput callback may be ** invoked by the sessions module at any point during the lifetime of the ** iterator. If such an xInput callback returns an error, the iterator enters ** an error state, whereby all subsequent calls to iterator functions ** immediately fail with the same error code as returned by xInput. ** Similarly, streaming API functions that return changesets (or patchsets) ** return them in chunks by way of a callback function instead of via a ** pointer to a single large buffer. In this case, a pair of parameters such ** as: *** <pre> ** &nbs; int *pnChangeset, ** &nbs; void **ppChangeset, ** </pre> *** Is replaced by: *** <pre> ** &nbs; int (*xOutput)(void *pOut, const void *pData, int nData), ** &nbs; void *pOut ** </pre> *** The xOutput callback is invoked zero or more times to return data to ** the application. The first parameter passed to each call is a copy of the ** pOut pointer supplied by the application. The second parameter, pData, ** points to a buffer nData bytes in size containing the chunk of output ** data being returned. If the xOutput callback successfully processes the ** supplied data, it should return SQLITE_OK to indicate success. Otherwise, ** it should return some other SQLite error code. In this case processing ** is immediately abandoned and the streaming API function returns a copy ** of the xOutput error code to the application. ** The sessions module never invokes an xOutput callback with the third ** parameter set to a value less than or equal to zero. Other than this, ** no guarantees are made as to the size of the chunks of data returned.

If the allocation ** fails, (*pRc) is set to SQLITE_NOMEM and NULL is returned.
80145. ** Mutex to control access to the memory allocation subsystem.
80146. Number of entries in aFirst[]
80147. ***** Below this point is the implementation of the fts5_decode() scalar ** function only.
80148. ** CAPI3REF: Return The Size Of An Open BLOB ** METHOD: sqlite3_blob ** ** ^Returns the size in bytes of the BLOB accessible via the ** successfully opened [BLOB handle] in its only argument. ^The ** incremental blob I/O routines can only read or overwriting existing ** blob content; they cannot change the size of a blob. ** ** This routine only works on a [BLOB handle] which has been created ** by a prior successful call to [sqlite3_blob_open()] and which has not ** been closed by [sqlite3_blob_close()]. Passing any other pointer in ** to this routine results in undefined and probably undesirable behavior.
80149. ** SQLite supports many different ways to resolve a constraint ** error. ROLLBACK processing means that a constraint violation ** causes the operation in process to fail and for the current transaction ** to be rolled back. ABORT processing means the operation in process ** fails and any prior changes from that one operation are backed out, ** but the transaction is not rolled back. FAIL processing means that ** the operation in progress stops and returns an error code. But prior ** changes due to the same operation are not backed out and no rollback ** occurs. IGNORE means that the particular row that caused the constraint ** error is not inserted or updated. Processing continues and no error ** is returned. REPLACE means that preexisting database rows that caused ** a UNIQUE constraint violation are removed so that the new insert or ** update can proceed. Processing continues and no error is reported. ** ** RESTRICT, SETNULL, and CASCADE actions apply only to foreign keys. ** RESTRICT is the same as ABORT for IMMEDIATE foreign keys and the ** same as ROLLBACK for DEFERRED keys. SETNULL means that the foreign ** key is set to NULL. CASCADE means that a DELETE or UPDATE of the ** referenced table row is propagated into the row that holds the ** foreign key. ** ** The following symbolic values are used to record which type ** of action to take.
80150. ** The input pointer currently points to the second byte of a table-header. ** Specifically, to the following: ** ** + number of columns in table (varint) ** + array of PK flags (1 byte per column), ** + table name (nul terminated). ** ** This function decodes the table-header and populates the p->nCol, ** p->zTab and p->abPK[] variables accordingly. The p->apValue[] array is ** also allocated or resized according to the new value of p->nCol. The ** input pointer is left pointing to the byte following the table header. ** ** If successful, SQLITE_OK is returned. Otherwise, an SQLite error code ** is returned and the final values of the various fields enumerated above ** are undefined.
80151. **comment:** Issue SQLITE_READ authorizations with a fake column name for any tables that ** are referenced but from which no values are extracted. Examples of where these ** kinds of null SQLITE_READ authorizations would occur: ** ** SELECT count(*) FROM t1; -- SQLITE_READ t1.**" ** SELECT t1.* FROM t1, t2; -- SQLITE_READ t2."** ** The fake column name is an empty string. It is possible for a table to ** have a column named by the empty string, in which case there is no way to ** distinguish between an unreferenced table and an actual reference to the ** "" column. The original design was for the fake column name to be a NULL, ** which would be unambiguous. But legacy authorization callbacks might ** assume the column name is non-NUL and segfault. The use of an empty string ** for the fake column name seems safer.

80490. **comment:** ** CAPI3REF: Setting The Result Of An SQL Function ** METHOD: sqlite3_context ** ** These routines are used by the xFunc or xFinal callbacks that ** implement SQL functions and aggregates. See ** [sqlite3_create_function()] and [sqlite3_create_function16()] ** for additional information. ** ** These functions work very much like the [parameter binding] family of ** functions used to bind values to host parameters in prepared statements. ** Refer to the [SQL parameter] documentation for additional information. ** ** ^The sqlite3_result_blob() interface sets the result from ** an application-defined function to be the BLOB whose content is pointed ** to by the second parameter and which is N bytes long where N is the ** third parameter. ** ** ^The sqlite3_result_zeroblob(C,N) and sqlite3_result_zeroblob64(C,N) ** interfaces set the result of the application-defined function to be ** a BLOB containing all zero bytes and N bytes in size. ** ** ^The sqlite3_result_double() interface sets the result from ** an application-defined function to be a floating point value specified ** by its 2nd argument. ** ** ^The sqlite3_result_error() and sqlite3_result_error16() functions ** cause the implemented SQL function to throw an exception. ** ^SQLite uses the string pointed to by the ** 2nd parameter of sqlite3_result_error() or sqlite3_result_error16() ** as the text of an error message. ^SQLite interprets the error ** message string from sqlite3_result_error() as UTF-8. ^SQLite ** interprets the string from sqlite3_result_error16() as UTF-16 in native ** byte order. ^If the third parameter to sqlite3_result_error() ** or sqlite3_result_error16() is negative then SQLite takes as the error ** message all text up through the first zero character. ** ^If the third parameter to sqlite3_result_error() or ** sqlite3_result_error16() is non-negative then SQLite takes that many ** bytes (not characters) from the 2nd parameter as the error message. ** ^The sqlite3_result_error() and sqlite3_result_error16() ** routines make a private copy of the error message text before ** they return. Hence, the calling function can deallocate or ** modify the text after they return without harm. ** ^The sqlite3_result_error_code() function changes the error code ** returned by SQLite as a result of an error in a function. ^By default, ** the error code is SQLITE_ERROR. ^A subsequent call to sqlite3_result_error() ** or sqlite3_result_error16() resets the error code to SQLITE_ERROR. ** ** ^The sqlite3_result_error_toobig() interface causes SQLite to throw an ** error indicating that a string or BLOB is too long to represent. ** ** ^The sqlite3_result_error_nomem() interface causes SQLite to throw an ** error indicating that a memory allocation failed. ** ** ^The sqlite3_result_int() interface sets the return value ** of the application-defined function to be the 32-bit signed integer ** value given in the 2nd argument. ** ^The sqlite3_result_int64() interface sets the return value ** of the application-defined function to be the 64-bit signed integer ** value given in the 2nd argument. ** ** ^The sqlite3_result_null() interface sets the return value ** of the application-defined function to be NULL. ** ** ^The sqlite3_result_text(), sqlite3_result_text16(), ** sqlite3_result_text16e(), and sqlite3_result_text16be() interfaces ** set the return value of the application-defined function to be ** a text string which is represented as UTF-8, UTF-16 native byte order, ** UTF-16 little endian, or UTF-16 big endian, respectively. ** ^The sqlite3_result_text64() interface sets the return value of an ** application-defined function to be a text string in an encoding ** specified by the fifth (and last) parameter, which must be one ** of [SQLITE_UTF8], [SQLITE_UTF16], [SQLITE_UTF16BE], or [SQLITE_UTF16LE]. ** ^SQLite takes the text result from the application from ** the 2nd parameter of the sqlite3_result_text* interfaces. ** ^If the 3rd parameter to the sqlite3_result_text* interfaces ** is negative, then SQLite takes result text from the 2nd parameter ** through the first zero character. ** ^If the 3rd parameter to the sqlite3_result_text* interfaces ** is non-negative, then as many bytes (not characters) of the text ** pointed to by the 2nd parameter are taken as the application-defined ** function result. If the 3rd parameter is non-negative, then it ** must be the byte offset into the string where the NUL terminator would ** appear if the string where NUL terminated. If any NUL characters occur ** in the string at a byte offset that is less than the value of the 3rd ** parameter, then the resulting string will contain embedded NULs and the ** result of expressions operating on strings with embedded NULs is undefined. ** ^If the 4th parameter to the sqlite3_result_text* interfaces ** or sqlite3_result_blob is a non-NULL pointer, then SQLite calls that ** function as the destructor on the text or BLOB result when it has ** finished using that result. ** ^If the 4th parameter to the sqlite3_result_text* interfaces or to ** sqlite3_result_blob is the special constant SQLITE_STATIC, then SQLite ** assumes that the text or BLOB result is in constant space and does not ** copy the content of the parameter nor call a destructor on the content ** when it has finished using that result. ** ^If the 4th parameter to the sqlite3_result_text* interfaces ** or sqlite3_result_blob is the special constant SQLITE_TRANSIENT ** then SQLite makes a copy of the result into space obtained ** from [sqlite3_malloc()] before it returns. ** ** ^The sqlite3_result_value() interface sets the result of ** the application-defined function to be a copy of the [sqlite3_value] object specified by the 2nd parameter. ^The ** sqlite3_result_value() interface makes a copy of the [sqlite3_value] ** so that the [sqlite3_value] specified in the parameter may change or ** be deallocated after sqlite3_result_value() returns without harm. ** ^A [protected] sqlite3_value] object may always be used where an ** [unprotected sqlite3_value] object is required, so either ** kind of [sqlite3_value] object can be used with this interface. ** ** ^The sqlite3_result_pointer(C,P,T,D) interface sets the result to an ** SQL NULL value, just like [sqlite3_result_null(C)], except that it ** also associates the host-language pointer P or type T with that ** NULL value such that the pointer can be retrieved within an ** [application-defined SQL function] using [sqlite3_value_pointer()]. ** ^If the D parameter is not NULL, then it is a pointer to a destructor ** for the P parameter. ^SQLite invokes D with P as its only argument ** when SQLite is finished with P. The T parameter should be a static ** string and preferably a string literal. The sqlite3_result_pointer() ** routine is part of the [pointer passing interface] added for SQLite 3.20.0. ** ** If these routines are called from within the different thread ** than the one containing the application-defined function that received ** the [sqlite3_context] pointer, the results are undefined.**label:** code-design

80491. ** CAPI3REF: OS Interface Open File Handle ** ** An [sqlite3_file] object represents an open file in the ** [sqlite3_vfs | OS interface layer]. Individual OS interface ** implementations will ** want to subclass this object by appending additional fields ** for their own use. The pMethods entry is a pointer to an ** [sqlite3_io_methods] object that defines methods for performing ** I/O operations on the open file.

80492. **comment:** ** EXTENSION API FUNCTIONS ** ** xUserData(pFts): ** Return a copy of the context pointer the extension function was ** registered with. ** ** xColumnTotalSize(pFts, iCol, pnToken): ** If parameter iCol is less than zero, set output variable *pnToken ** to the total number of tokens in the FTS5 table. Or, if iCol is ** non-negative but less than the number of columns in the table, return ** the total number of tokens in column iCol, considering all rows in ** the FTS5 table. ** ** If parameter iCol is greater than or equal to the number of columns ** in the table, SQLITE_RANGE is returned. Or, if an error occurs (e.g. ** an OOM condition or IO error), an appropriate SQLite error code is ** returned. ** ** xColumnCount(pFts): ** Return the number of columns in the table. ** ** xColumnSize(pFts, iCol, pnToken): ** If parameter iCol is less than zero, set output variable *pnToken ** to the total number of tokens in the current row. Or, if iCol is ** non-negative but less than the number of columns in the table, set ** *pnToken to the number of tokens in column iCol of the current row. ** ** If parameter iCol is greater than or equal to the number of columns ** in the table, SQLITE_RANGE is returned. Or, if an error occurs (e.g. ** an OOM condition or IO error), an appropriate SQLite error code is ** returned. ** ** This function may be quite inefficient if used with an FTS5 table ** created with the "columnsize=0" option. ** ** xColumnText: ** This function attempts to retrieve the text of column iCol of the ** current document. If successful, (*pz) is set to point to a buffer ** containing the text in utf-8 encoding, (*pn) is set to the size in bytes ** (not characters) of the buffer and SQLITE_OK is returned. Otherwise, ** if an error occurs, an SQLite error code is returned and the final values ** of (*pz) and (*pn) are undefined. ** ** xPhraseCount: ** Returns the number of phrases in the current query expression. ** ** xPhraseSize: ** Returns the number of tokens in phrase iPhrase of the query. Phrases ** are numbered starting from zero. ** ** xInstCount: ** Set *pnInst to the total number of occurrences of all phrases within ** the query within the current row. Return SQLITE_OK if successful, or ** an error code (i.e. SQLITE_NOMEM) if an error occurs. ** ** This API can be quite slow if used with an FTS5 table created with the ** "detail=None" or "detail=column" option. If the FTS5 table is created ** with either "detail=None" or "detail=column" and "content=" option ** (i.e. if it is a contentless table), then this API always returns 0. ** ** xInst: ** Query for the details of phrase match iIdx within the current row. ** Phrase matches are

numbered starting from zero, so the iIdx argument ** should be greater than or equal to zero and smaller than the value ** output by xInstCount(). *** Usually, output parameter *piPhrase is set to the phrase number, *piCol ** to the column in which it occurs and *piOff the token offset of the ** first token of the phrase. The exception is if the table was created ** with the offsets=0 option specified. In this case *piOff is always ** set to -1. *** Returns SQLITE_OK if successful, or an error code (i.e. SQLITE_NOMEM) ** if an error occurs. *** This API can be quite slow if used with an FTS5 table created with the ** "detail=None" or "detail=column" option. *** xRowid: ** Returns the rowid of the current row. *** xTokenize: ** Tokenize text using the tokenizer belonging to the FTS5 table. *** xQueryPhrase(pFts5, iPhrase, pUserData, xCallback): ** This API function is used to query the FTS table for phrase iPhrase ** of the current query. Specifically, a query equivalent to: *** ... FROM ftstable WHERE ftstable MATCH \$p ORDER BY rowid ** with \$p set to a phrase equivalent to the phrase iPhrase of the ** current query is executed. Any column filter that applies to ** phrase iPhrase of the current query is included in \$p. For each ** row visited, the callback function passed as the fourth argument ** is invoked. The context and API objects passed to the callback ** function may be used to access the properties of each matched row. ** Invoking Api.xUserData() returns a copy of the pointer passed as ** the third argument to pUserData. *** If the callback function returns any value other than SQLITE_OK, the ** query is abandoned and the xQueryPhrase function returns immediately. ** If the returned value is SQLITE_DONE, xQueryPhrase returns SQLITE_OK. ** Otherwise, the error code is propagated upwards. *** If the query runs to completion without incident, SQLITE_OK is returned. ** Or, if some error occurs before the query completes or is aborted by ** the callback, an SQLite error code is returned. *** *** xSetAuxdata(pFts5, pAux, xDelete) ** Save the pointer passed as the second argument as the extension functions ** "auxiliary data". The pointer may then be retrieved by the current or any ** future invocation of the same fts5 extension function made as part of ** of the same MATCH query using the xGetAuxdata() API. *** Each extension function is allocated a single auxiliary data slot for ** each FTS query (MATCH expression). If the extension function is invoked ** more than once for a single FTS query, then all invocations share a ** single auxiliary data context. *** If there is already an auxiliary data pointer when this function is ** invoked, then it is replaced by the new pointer. If an xDelete callback ** was specified along with the original pointer, it is invoked at this ** point. *** The xDelete callback, if one is specified, is also invoked on the ** auxiliary data pointer after the FTS5 query has finished. *** If an error (e.g. an OOM condition) occurs within this function, an ** the auxiliary data is set to NULL and an error code returned. If the ** xDelete parameter was not NULL, it is invoked on the auxiliary data ** pointer before returning. *** xGetAuxdata(pFts5, bClear) ** Returns the current auxiliary data pointer for the fts5 extension ** function. See the xSetAuxdata() method for details. *** If the bClear argument is non-zero, then the auxiliary data is cleared ** (set to NULL) before this function returns. In this case the xDelete, ** if any, is not invoked. *** xRowCount(pFts5, pnRow) ** This function is used to retrieve the total number of rows in the table. ** In other words, the same value that would be returned by: *** SELECT count(*) FROM ftstable; *** xPhraseFirst() ** This function is used, along with type Fts5PhraseIter and the xPhraseNext() ** method, to iterate through all instances of a single query phrase within ** the current row. This is the same information as is accessible via the ** xInstCount/xInst APIs. While the xInstCount/xInst APIs are more convenient ** to use, this API may be faster under some circumstances. To iterate ** through instances of phrase iPhrase, use the following code: *** Fts5PhraseIter iter; ** int iCol, iOff; ** for(pApi->xPhraseFirst(pFts, iPhrase, &iter, &iCol, &iOff); ** iCol>=0; ** pApi->xPhraseNext(pFts, &iter, &iCol, &iOff) **) { ** // An instance of phrase iPhrase at offset iOff of column iCol ** } *** The Fts5PhraseIter structure is defined above. Applications should not ** modify this structure directly - it should only be used as shown above ** with the xPhraseFirst() and xPhraseNext() API methods (and by ** xPhraseFirstColumn() and xPhraseNextColumn() as illustrated below). *** This API can be quite slow if used with an FTS5 table created with the ** "detail=None" or "detail=column" option. If the FTS5 table is created ** with either "detail=None" or "detail=column" and "content=" option ** (i.e. if it is a contentless table), then this API always iterates ** through an empty set (all calls to xPhraseFirst() set iCol to -1). *** xPhraseNext() ** See xPhraseFirst above. *** xPhraseFirstColumn() ** This function and xPhraseNextColumn() are similar to the xPhraseFirst() ** and xPhraseNext() APIs described above. The difference is that instead ** of iterating through all instances of a phrase in the current row, these ** APIs are used to iterate through the set of columns in the current row ** that contain one or more instances of a specified phrase. For example: *** Fts5PhraseIter iter; ** int iCol; ** for(pApi->xPhraseFirstColumn(pFts, iPhrase, &iter, &iCol); ** iCol>=0; ** pApi->xPhraseNextColumn(pFts, &iter, &iCol) **) { ** // Column iCol contains at least one instance of phrase iPhrase ** } *** This API can be quite slow if used with an FTS5 table created with the ** "detail=None" option. If the FTS5 table is created with either ** "detail=None" "content=" option (i.e. if it is a contentless table), ** then this API always iterates through an empty set (all calls to ** xPhraseFirstColumn() set iCol to -1). *** The information accessed using this API and its companion ** xPhraseFirstColumn() may also be obtained using xPhraseFirst/xPhraseNext ** (or xInst/xInstCount). The chief advantage of this API is that it is ** significantly more efficient than those alternatives when used with ** "detail=column" tables. *** xPhraseNextColumn() ** See xPhraseFirstColumn above.

80495. Source database name

80496. Pointer to application-specific data

80497. ** CAPI3REF: Obtaining SQL Values ** METHOD: sqlite3_value ** ** Summary: ** <blockquote><table border=0 cellpadding=0 cellspacing=0> ** <tr><td>sqlite3_value_blob</td>→;<td>BLOB value **
<td>sqlite3_value_double</td>→;<td>REAL value **
<td>sqlite3_value_int</td>→;<td>32-bit INTEGER value **
<td>sqlite3_value_int64</td>→;<td>64-bit INTEGER value **
<td>sqlite3_value_pointer</td>→;<td>Pointer value **
<td>sqlite3_value_text</td>→;<td>UTF-8 TEXT value **
<td>sqlite3_value_text16</td>→;<td>UTF-16 TEXT value in ** the native byteorder **
<td>sqlite3_value_text16be</td>→;<td>UTF-16be TEXT value **
<td>sqlite3_value_text16le</td>→;<td>UTF-16le TEXT value **
<td> <td> <td> <td>
<td>sqlite3_value_bytes</td>→;<td>Size of a BLOB ** or a UTF-8 TEXT in bytes **
<td>sqlite3_value_type</td>→;<td>Default ** datatype of the value **
<td>sqlite3_value_numeric_type</td>→;<td>Best numeric datatype of the value ** </table></blockquote> ** ** Details: ** ** These routines extract type, size, and content information from ** [protected sqlite3_value] objects. Protected sqlite3_value objects ** are used to pass parameter information into implementation of ** [application-defined SQL functions] and [virtual tables]. ** ** These routines work only with [protected sqlite3_value] objects. ** Any attempt to use these routines on an [unprotected sqlite3_value] ** is not threadsafe. ** ** ^These routines work just like the corresponding [column access functions] ** except that these routines take a single [protected sqlite3_value] object ** pointer instead of a [sqlite3_stmt] pointer and an integer column number. ** ** ^The sqlite3_value_text16() interface extracts a UTF-16 string ** in the native byte-order of the host machine. ^The ** sqlite3_value_text16be() and sqlite3_value_text16le() interfaces ** extract UTF-16 strings as big-endian and little-endian respectively. ** ** ^If [sqlite3_value] object V was initialized ** using [sqlite3_bind_pointer(S,I,P,X,D)] or [sqlite3_result_pointer(C,P,X,D)] ** and if X and Y are strings that compare equal according to strcmp(X,Y), ** then sqlite3_value_pointer(V,Y) will return the pointer P. ^Otherwise, ** sqlite3_value_pointer(V,Y) returns a NULL. The sqlite3_bind_pointer() ** routine is part of the [pointer passing interface] added for SQLite 3.20.0. ** ** ^^(The sqlite3_value_type(V) interface returns the ** [SQLITE_INTEGER | datatype code] for the initial datatype of the ** [sqlite3_value] object V. The returned value is one of [SQLITE_INTEGER], ** [SQLITE_FLOAT], [SQLITE_TEXT], [SQLITE_BLOB], or [SQLITE_NULL].)^ ** Other interfaces might change the datatype for an sqlite3_value object. ** For example, if the datatype is initially SQLITE_INTEGER and ** sqlite3_value_text(V) is called to extract a text value for that ** integer, then subsequent calls to sqlite3_value_type(V) might return ** SQLITE_TEXT. Whether or not a persistent internal datatype conversion ** occurs is undefined and may change from one release of SQLite to the next. ** ** ^^(The sqlite3_value_numeric_type() interface attempts to apply ** numeric affinity to the value. This means that an attempt is ** made to convert the value to an integer or floating point. If ** such a conversion is possible without loss of information (in other ** words, if the value is a string that looks like a number) ** then the conversion is performed. Otherwise no conversion occurs. ** The [SQLITE_INTEGER | datatype] after conversion is returned.)^ ** Please pay particular attention to the fact that the pointer returned ** from [sqlite3_value_blob()], [sqlite3_value_text()], or ** [sqlite3_value_text16()] can be invalidated by a subsequent call to ** [sqlite3_value_bytes()], [sqlite3_value_bytes16()], [sqlite3_value_text16()], ** or [sqlite3_value_text16()]. ** ** These routines must be called from the same thread as ** the SQL function that supplied the [sqlite3_value*] parameters.

80498. ** CAPI3REF: Extract Metadata About A Column Of A Table ** METHOD: sqlite3 *** ** ^^(The sqlite3_table_column_metadata(X,D,T,C,...) routine returns ** information about column C of table T in database D ** on [database connection] X.)^ ** The sqlite3_table_column_metadata() ** interface returns SQLITE_OK and fills in the non-NULL pointers in ** the final five arguments with appropriate values if the specified ** column exists. ^The sqlite3_table_column_metadata() interface returns ** SQLITE_ERROR and if the specified column does not exist. ** ^If the column-name parameter to sqlite3_table_column_metadata() is a ** NULL pointer, then this routine simply checks for the existence of the ** table and returns SQLITE_OK if the table exists and SQLITE_ERROR if it ** does not. If the table name parameter T in a call to ** sqlite3_table_column_metadata(X,D,T,C,...) is NULL then the result is ** undefined behavior. *** ^The column is identified by the second, third and fourth parameters to ** this function. ^^(The second parameter is either the name of the database ** (i.e. "main", "temp", or an attached database) containing the specified ** table or NULL.)^ ** If it is NULL, then all attached databases are searched ** for the table using the same algorithm used by the database engine to ** resolve unqualified table references. ** ** ^^(The third and fourth parameters to this function are the table and column ** name of the desired column, respectively. ** ** ^Metadata is returned by writing to the memory locations passed as the 5th ** and subsequent parameters to this function. ^Any of these arguments may be ** NULL, in which case the corresponding element of metadata is omitted. ** ** ^<blockquote> ** <table border="1"> **
<th> Parameter <th> Output
<th> Type <th> Description ** **
<td> 5th <td> const char* <td> Data type **
<td> 6th <td> const char* <td> Name of default collation sequence **
<td> 7th <td> int <td> True if column has a NOT NULL constraint **
<td> 8th <td> int <td> True if column is part of the PRIMARY KEY **
<td> 9th <td> int <td> True if column is [AUTOINCREMENT] ** </table> ** </blockquote>)*** ^^(The memory pointed to by the

character pointers returned for the ** declaration type and collation sequence is valid until the next ** call to any SQLite API function. *** ^If the specified table is actually a view, an [error code] is returned. *** ^If the specified column is "rowid", "oid" or "_rowid_" and the table ** is not a [WITHOUT ROWID] table and an ** [INTEGER PRIMARY KEY] column has been explicitly declared, then the output ** parameters are set for the explicitly declared column. ^If there is no ** [INTEGER PRIMARY KEY] column, then the outputs ** for the [rowid] are set as follows: *** <pre> ** data type: "INTEGER" ** collation sequence: "BINARY" ** not null: 0 ** primary key: 1 ** auto increment: 0 ** </pre> *** ^This function causes all database schemas to be read from disk and ** parsed, if that has not already been done, and returns an error if ** any errors are encountered while loading the schema.

80499. ** CAPI3REF: Test if a changeset has recorded any changes. *** Return non-zero if no changes to attached tables have been recorded by ** the session object passed as the first argument. Otherwise, if one or ** more changes have been recorded, return zero. *** Even if this function returns zero, it is possible that calling ** [sqlite3session_changeset()] on the session handle may still return a ** changeset that contains no changes. This can happen when a row in ** an attached table is modified and then later on the original values ** are restored. However, if this function returns non-zero, then it is ** guaranteed that a call to sqlite3session_changeset() will return a ** changeset containing zero changes.

80500. int *psz

80501. ** CAPI3REF: Text Encodings *** These constant define integer codes that represent the various ** text encodings supported by SQLite.

80502. ** CAPI3REF: Evaluate An SQL Statement ** METHOD: sqlite3_stmt ** After a [prepared statement] has been prepared using any of ** [sqlite3_prepare_v2()], [sqlite3_prepare_v3()], [sqlite3_prepare16_v2()] or ** or [sqlite3_prepare16_v3()] or one of the legacy ** interfaces [sqlite3_prepare()] or [sqlite3_prepare16()], this function ** must be called one or more times to evaluate the statement. *** The details of the behavior of the sqlite3_step() interface depend ** on whether the statement was prepared using the newer "vX" interfaces ** [sqlite3_prepare_v3()], [sqlite3_prepare_v2()], [sqlite3_prepare16_v3()] or ** [sqlite3_prepare16_v2()] or the older legacy ** interfaces [sqlite3_prepare()] and [sqlite3_prepare16()]. The use of the ** new "vX" interface is recommended for new applications but the legacy ** interface will continue to be supported. *** ^In the legacy interface, the return value will be either [SQLITE_BUSY], ** [SQLITE_DONE], [SQLITE_ROW], [SQLITE_ERROR], or [SQLITE_MISUSE]. ** ^With the "v2" interface, any of the other [result codes] or ** [extended result codes] might be returned as well. *** ^[SQLITE_BUSY] means that the database engine was unable to acquire the ** database locks it needs to do its job. ^If the statement is a [COMMIT] ** or occurs outside of an explicit transaction, then you can retry the ** statement. If the statement is not a [COMMIT] and occurs within an ** explicit transaction then you should rollback the transaction before ** continuing. *** ^[SQLITE_DONE] means that the statement has finished executing ** successfully. sqlite3_step() should not be called again on this virtual ** machine without first calling [sqlite3_reset()] to reset the virtual ** machine back to its initial state. *** ^If the SQL statement being executed returns any data, then [SQLITE_ROW] ** is returned each time a new row of data is ready for processing by the ** caller. The values may be accessed using the [column access functions]. ** sqlite3_step() is called again to retrieve the next row of data. *** ^[SQLITE_ERROR] means that a run-time error (such as a constraint ** violation) has occurred. sqlite3_step() should not be called again on ** the VM. More information may be found by calling [sqlite3_errmsg()]. ** ^With the legacy interface, a more specific error code (for example, ** [SQLITE_INTERRUPT], [SQLITE_SCHEMA], [SQLITE_CORRUPT], and so forth) ** can be obtained by calling [sqlite3_reset()] on the ** [prepared statement]. ^In the "v2" interface, ** the more specific error code is returned directly by sqlite3_step(). ** ^[SQLITE_MISUSE] means that this routine was called inappropriately. ** Perhaps it was called on a [prepared statement] that has ** already been [sqlite3_finalize | finalized] or on one that had ** previously returned [SQLITE_ERROR] or [SQLITE_DONE]. Or it could ** be the case that the same database connection is being used by two or ** more threads at the same moment in time. *** ^For all versions of SQLite up to and including 3.6.23.1, a call to ** [sqlite3_reset()] was required after sqlite3_step() returned anything ** other than [SQLITE_ROW] before any subsequent invocation of ** sqlite3_step(). Failure to reset the prepared statement using ** [sqlite3_reset()] would result in an [SQLITE_MISUSE] return from ** sqlite3_step(). But after [version 3.6.23.1] ([dateof:3.6.23.1]), ** sqlite3_step() began ** calling [sqlite3_reset()] automatically in this circumstance rather ** than returning [SQLITE_MISUSE]. This is not considered a compatibility ** break because any application that ever receives an [SQLITE_MISUSE] error ** is broken by definition. The [SQLITE_OMIT_AUTORESET] compile-time option ** can be used to restore the legacy behavior. *** Goofy Interface Alert: In the legacy interface, the sqlite3_step() ** API always returns a generic error code, [SQLITE_ERROR], following any ** error other than [SQLITE_BUSY] and [SQLITE_MISUSE]. You must call ** [sqlite3_reset()] or [sqlite3_finalize()] in order to find one of the ** specific [error codes] that better describes the error. ** We admit that this is a goofy design. The problem has been fixed ** with the "v2" interface. If you prepare all of your SQL statements ** using [sqlite3_prepare_v3()] or [sqlite3_prepare_v2()] ** or [sqlite3_prepare16_v2()] or [sqlite3_prepare16_v3()] instead ** of the legacy [sqlite3_prepare()] and [sqlite3_prepare16()] interfaces, ** then the more specific [error codes] are returned directly ** by sqlite3_step(). The use of the "vX" interfaces is recommended.

80503. ** CAPI3REF: String LIKE Matching * ** ^The [sqlite3_strlike(P,X,E)] interface returns zero if and only if ** string X matches the [LIKE] pattern P with escape character E. ** ^The definition of [LIKE] pattern matching used in ** [sqlite3_strlike(P,X,E)] is the same as for the "X LIKE P ESCAPE E" ** operator in the SQL dialect understood by SQLite. ^For "X LIKE P" without ** the ESCAPE clause, set the E parameter of [sqlite3_strlike(P,X,E)] to 0. ** ^As with the LIKE operator, the [sqlite3_strlike(P,X,E)] function is case ** insensitive - equivalent upper and lower case ASCII characters match ** one another. *** ^The [sqlite3_strlike(P,X,E)] function matches Unicode characters, though ** only ASCII characters are case folded. *** ^Note that this routine returns zero on a match and non-zero if the strings ** do not match, the same as [sqlite3_strcmp()] and [sqlite3_strncmp()]. *** See also: [sqlite3_strglob()].

80504. ** Specify the key for an encrypted database. This routine should be ** called right after sqlite3_open(). *** The code to implement this API is not available in the public release ** of SQLite.

80505. Database lock protocol error

80506. ** CAPI3REF: Checkpoint a database ** METHOD: sqlite3 *** ^The sqlite3_wal_checkpoint_v2(D,X,M,L,C) interface runs a checkpoint ** operation on database X of [database connection] D in mode M. Status ** information is written back into integers pointed to by L and C. ^ ** ^The M parameter must be a valid [checkpoint mode]:*** <dl> ** <dt>SQLITE_CHECKPOINT_PASSIVE<dd> ** ^Checkpoint as many frames as possible without waiting for any database ** readers or writers to finish, then sync the database file if all frames ** in the log were checkpointed. ^The [busy-handler callback] ** is never invoked in the SQLITE_CHECKPOINT_PASSIVE mode. ** ^On the other hand, passive mode might leave the checkpoint unfinished ** if there are concurrent readers or writers. *** <dt>SQLITE_CHECKPOINT_FULL<dd> ** ^This mode blocks (it invokes the ** [sqlite3_busy_handler|busy-handler callback]) until there is no ** database writer and all readers are reading from the most recent database ** snapshot. ^It then checkpoints all frames in the log file and syncs the ** database file. ^This mode blocks new database writers while it is pending, ** but new database readers are allowed to continue unimpeded. *** <dt>SQLITE_CHECKPOINT_RESTART<dd> ** ^This mode works the same way as SQLITE_CHECKPOINT_FULL with the addition ** that after checkpointing the log file it blocks (calls the ** [busy-handler callback]) ** until all readers are reading from the database file only. ^This ensures ** that the next writer will restart the log file from the beginning. ** ^Like SQLITE_CHECKPOINT_FULL, this mode blocks new ** database writer attempts while it is pending, but does not impede readers. *** <dt>SQLITE_CHECKPOINT_TRUNCATE<dd> ** ^This mode works the same way as SQLITE_CHECKPOINT_RESTART with the ** addition that it also truncates the log file to zero bytes just prior ** to a successful return. ** </dt> *** ^If pnLog is not NULL, then *pnLog is set to the total number of frames in ** the log file or to -1 if the checkpoint could not run because ** of an error or because the database is not in [WAL mode]. ^If pnCkpt is not ** NULL, then *pnCkpt is set to the total number of checkpointed frames in the ** log file (including any that were already checkpointed before the function ** was called) or to -1 if the checkpoint could not run due to an error or ** because the database is not in WAL mode. ^Note that upon successful ** completion of an SQLITE_CHECKPOINT_TRUNCATE, the log file will have been ** truncated to zero bytes and so both *pnLog and *pnCkpt will be set to zero. *** ^All calls obtain an exclusive "checkpoint" lock on the database file. ^If ** any other process is running a checkpoint operation at the same time, the ** lock cannot be obtained and SQLITE_BUSY is returned. ^Even if there is a ** busy-handler configured, it will not be invoked in this case. *** ^The SQLITE_CHECKPOINT_FULL, RESTART and TRUNCATE modes also obtain the ** exclusive "writer" lock on the database file. ^If the writer lock cannot be ** obtained immediately, and a busy-handler is configured, it is invoked and ** the writer lock retried until either the busy-handler returns 0 or the lock ** is successfully obtained. ^The busy-handler is also invoked while waiting for ** database readers as described above. ^If the busy-handler returns 0 before ** the writer lock is obtained or while waiting for database readers, the ** checkpoint operation proceeds from that point in the same way as ** SQLITE_CHECKPOINT_PASSIVE - checkpointing as many frames as possible ** without blocking any further. ^SQLITE_BUSY is returned in this case. *** ^If parameter zDb is NULL or points to a zero length string, then the ** specified operation is attempted on all WAL databases [attached] to ** [database connection] db. In this case the ** values written to output parameters *pnLog and *pnCkpt are undefined. ^If ** an SQLITE_BUSY error is encountered when processing one or more of the ** attached WAL databases, the operation is still attempted on any remaining ** attached databases and SQLITE_BUSY is returned at the end. ^If any other ** error occurs while processing an attached database, processing is abandoned ** and the error code is returned to the caller immediately. ^If no error ** (SQLITE_BUSY or otherwise) is encountered while processing the attached ** databases, SQLITE_OK is returned. *** ^If database zDb is the name of an attached database that is not in WAL ** mode, SQLITE_OK is returned and both *pnLog and *pnCkpt set to -1. ^If ** zDb is not NULL (or a zero length string) and is not the name of any ** attached database, SQLITE_ERROR is returned to the caller. *** ^Unless it returns SQLITE_MISUSE, ** the sqlite3_wal_checkpoint_v2() interface ** sets the error information that is queried by ** [sqlite3_errcode()] and [sqlite3_errmsg()]. *** ^The [PRAGMA wal_checkpoint] command can be used to invoke this interface ** from SQL.

80507. ** CAPI3REF: Virtual Table Constraint Operator Codes *** These macros defined the allowed values for the ** [sqlite3_index_info].aConstraint[].op field. Each value represents ** an operator that is part of a constraint term in the wHERE clause of ** a query that uses a [virtual table].

80508. Unknown opcode in sqlite3_file_control()

80509. sqlite3_pcache_methods2*

80510. ** CAPI3REF: Finding The Subtype Of SQL Values ** METHOD: sqlite3_value ** ** ^The sqlite3_value_subtype(V) function returns the subtype for ** an [application-defined SQL function] argument V. The subtype ** information can be used to pass a limited amount of context from ** one SQL function to another. Use the [sqlite3_result_subtype()] ** routine to set the subtype for the return value of an SQL function.

80511. xFunc, void*

80512. ** CAPI3REF: Enable Or Disable Shared Pager Cache ** ** ^This routine enables or disables the sharing of the database cache ** and schema data structures between [database connection | connections] ** to the same database. Sharing is enabled if the argument is true ** and disabled if the argument is false.)^** ** ^Cache sharing is enabled and disabled for an entire process. ** This is a change as of SQLite [version 3.5.0] ([dateof:3.5.0]). ** In prior versions of SQLite, ** sharing was enabled or disabled for each thread separately. ** ** ^The cache sharing mode set by this interface effects all subsequent ** calls to [sqlite3_open0], [sqlite3_open_v20], and [sqlite3_open160]. ** Existing database connections continue use the sharing mode ** that was in effect at the time they were opened.)^** ** ^This routine returns [SQLITE_OK] if shared cache was enabled or disabled ** successfully. An [error code] is returned otherwise.)^** ** ^Shared cache is disabled by default. But this might change in ** future releases of SQLite. Applications that care about shared ** cache setting should set it explicitly. ** ** Note: This method is disabled on MacOS X 10.7 and iOS version 5.0 ** and will always return SQLITE_MISUSE. On those systems, ** shared cache mode should be enabled per-database connection via ** [sqlite3_open_v20] with [SQLITE_OPEN_SHAREDCACHE]. ** ** This interface is threadsafe on processors where writing a ** 32-bit integer is atomic. ** ** See Also: [SQLite Shared-Cache Mode]

80513. **comment:** ** CAPI3REF: Finalize A Changeset Iterator ** ** This function is used to finalize an iterator allocated with ** [sqlite3changeset_start()]. ** ** This function should only be called on iterators created using the ** [sqlite3changeset_start()] function. If an application calls this ** function with an iterator passed to a conflict-handler by ** [sqlite3changeset_apply0], [SQLITE_MISUSE] is immediately returned and the ** call has no effect. ** ** If an error was encountered within a call to an sqlite3changeset_xxx() ** function (for example an [SQLITE_CORRUPT] in [sqlite3changeset_next0] or an ** [SQLITE_NOMEM] in [sqlite3changeset_new0]) then an error code corresponding ** to that error is returned by this function. Otherwise, SQLITE_OK is ** returned. This is to allow the following pattern (pseudo-code): ** ** sqlite3changeset_start(); ** while(SQLITE_ROW==sqlite3changeset_next0()) { ** // Do something with change. ** } ** rc = sqlite3changeset_finalize(); ** if(rc!=SQLITE_OK) { ** // An error has occurred ** }

80514. End of the 'extern "C"' block

80515. ** CAPI3REF: Virtual Table Interface Configuration ** ** This function may be called by either the [xConnect] or [xCreate] method ** of a [virtual table] implementation to configure ** various facets of the virtual table interface. ** ** If this interface is invoked outside the context of an xConnect or ** xCreate virtual table method then the behavior is undefined. ** ** At present, there is only one option that may be configured using ** this function. (See [SQLITE_VTAB_CONSTRAINT_SUPPORT].) Further options ** may be added in the future.

80516. end of the 'extern "C"' block

80517. ** CAPI3REF: Cancel Automatic Extension Loading ** ** ^The [sqlite3_cancel_auto_extension(X)] interface unregisters the ** initialization routine X that was registered using a prior call to ** [sqlite3_auto_extension(X)]. ^The [sqlite3_cancel_auto_extension(X)] ** routine returns 1 if initialization routine X was successfully ** unregistered and it returns 0 if X was not on the list of initialization ** routines.

80518. ***** End of sqlite3tree.h *****

80519. ** CAPI3REF: Initialize The SQLite Library ** ** ^The sqlite3_initialize() routine initializes the ** SQLite library. ^The sqlite3_shutdown() routine ** deallocates any resources that were allocated by sqlite3_initialize(). ** These routines are designed to aid in process initialization and ** shutdown on embedded systems. Workstation applications using ** SQLite normally do not need to invoke either of these routines. ** ** A call to sqlite3_initialize() is an "effective" call if it is ** the first time sqlite3_initialize() is invoked during the lifetime of ** the process, or if it is the first time sqlite3_initialize() is invoked ** following a call to sqlite3_shutdown(). ^Only an effective call ** of sqlite3_initialize() does any initialization. All other calls ** are harmless no-ops.)^** ** A call to sqlite3_shutdown() is an "effective" call if it is the first ** call to sqlite3_shutdown() since the last sqlite3_initialize(). ^Only ** an effective call to sqlite3_shutdown() does any deinitialization. ** All other valid calls to sqlite3_shutdown() are harmless no-ops.)^** ** ^The sqlite3_initialize() interface is threadsafe, but sqlite3_shutdown() ** is not. The sqlite3_shutdown() interface must only be called from a ** single thread. All open [database connections] must be closed and all ** other SQLite resources must be deallocated prior to invoking ** sqlite3_shutdown0). ** ** Among other things, ^sqlite3_initialize() will invoke ** sqlite3_os_init(). Similarly, ^sqlite3_shutdown() ** will invoke sqlite3_os_end0). ** ** ^The sqlite3_initialize() routine returns [SQLITE_OK] on success. ** ^If for some reason, sqlite3_initialize() is unable to initialize ** the library (perhaps it is unable to allocate a needed resource such ** as a mutex) it returns an [error code] other than [SQLITE_OK]. ** ** ^The sqlite3_initialize() routine is called internally by many other ** SQLite interfaces so that an application usually does not need to ** invoke sqlite3_initialize() directly. For example, [sqlite3_open0] ** calls sqlite3_initialize() so the SQLite library will be automatically ** initialized when [sqlite3_open0] is called if it has not been initialized ** already. ^However, if SQLite is compiled with the [SQLITE_OMIT_AUTOINIT] ** compile-time option, then the automatic calls to sqlite3_initialize() ** are omitted and the application must call sqlite3_initialize() directly ** prior to using any other SQLite interface. For maximum portability, ** it is recommended that applications always invoke sqlite3_initialize() ** directly prior to using any other SQLite interface. Future releases ** of SQLite may require this. In other words, the behavior exhibited ** when SQLite is compiled with [SQLITE_OMIT_AUTOINIT] might become the ** default behavior in some future release of SQLite. ** ** The sqlite3_os_init() routine does operating-system specific ** initialization of the SQLite library. The sqlite3_os_end0) ** routine undoes the effect of sqlite3_os_init(). Typical tasks ** performed by these routines include allocation or deallocation ** of static resources, initialization of global variables, ** setting up a default [sqlite3_vfs] module, or setting up ** a default configuration using [sqlite3_config0]. ** ** The application should never invoke either sqlite3_os_init() ** or sqlite3_os_end0 directly. The application should only invoke ** sqlite3_initialize() and sqlite3_shutdown0). The sqlite3_os_init() ** interface is called automatically by sqlite3_initialize() and ** sqlite3_os_end() is called by sqlite3_shutdown0). Appropriate ** implementations for sqlite3_os_init() and sqlite3_os_end() ** are built into SQLite when it is compiled for Unix, Windows, or OS/2. ** When [custom builds | built for other platforms] ** (using the [SQLITE_OS_OTHER=1] compile-time ** option) the application must supply a suitable implementation for ** sqlite3_os_init() and sqlite3_os_end0). An application-supplied ** implementation of sqlite3_os_init() or sqlite3_os_end0) ** must return [SQLITE_OK] on success and some other [error code] upon ** failure.

80524. **comment:** **** * CUSTOM TOKENIZERS *** Applications may also register custom tokenizer types. A tokenizer ** is registered by providing fts5 with a populated instance of the ** following structure. All structure methods must be defined, setting ** any member of the fts5_tokenizer struct to NULL leads to undefined ** behaviour. The structure methods are expected to function as follows: ** ** xCreate: ** This function is used to allocate and initialize a tokenizer instance. ** A tokenizer instance is required to actually tokenize text. *** The first argument passed to this function is a copy of the (void*) ** pointer provided by the application when the fts5_tokenizer object ** was registered with FTS5 (the third argument to xCreateTokenizer()). ** The second and third arguments are an array of nul-terminated strings ** containing the tokenizer arguments, if any, specified following the ** tokenizer name as part of the CREATE VIRTUAL TABLE statement used ** to create the FTS5 table. *** The final argument is an output variable. If successful, (*ppOut) ** should be set to point to the new tokenizer handle and SQLITE_OK ** returned. If an error occurs, some value other than SQLITE_OK should ** be returned. In this case, fts5 assumes that the final value of *ppOut ** is undefined. *** ** xDelete: ** This function is invoked to delete a tokenizer handle previously ** allocated using xCreate(). Fts5 guarantees that this function will ** be invoked exactly once for each successful call to xCreate(). *** ** xTokenize: ** This function is expected to tokenize the nText byte string indicated ** by argument pText. pText may or may not be null-terminated. The first ** argument passed to this function is a pointer to an Fts5Tokenizer object ** returned by an earlier call to xCreate(). *** ** The second argument indicates the reason that FTS5 is requesting ** tokenization of the supplied text. This is always one of the following ** four values: ** ** <i> FTS5_TOKENIZE_DOCUMENT - A document is being inserted into ** or removed from the FTS table. The tokenizer is being invoked to ** determine the set of tokens to add to (or delete from) the ** FTS index. ** ** <i> FTS5_TOKENIZE_QUERY - A MATCH query is being executed ** against the FTS index. The tokenizer is being called to tokenize ** a bareword or quoted string specified as part of the query. ** ** <i> (FTS5_TOKENIZE_QUERY | FTS5_TOKENIZE_PREFIX) - Same as ** FTS5_TOKENIZE_QUERY, except that the bareword or quoted string is ** followed by a "" character, indicating that the last token ** returned by the tokenizer will be treated as a token prefix. ** ** <i> FTS5_TOKENIZE_AUX - The tokenizer is being invoked to ** satisfy an fts5_api.xTokenize() request made by an auxiliary ** function. Or an fts5_api.xColumnSize() request made by the same ** on a columnsize=0 database. ** *** ** For each token in the input string, the supplied callback xToken() must ** be invoked. The first argument to it should be a copy of the pointer ** passed as the second argument to xTokenize(). The third and fourth ** arguments are a pointer to a buffer containing the token text, and the ** size of the token in bytes. The 4th and 5th arguments are the byte offsets ** of the first byte of and first byte immediately following the text from ** which the token is derived within the input. *** ** The second argument passed to the xToken() callback ("tflags") should ** normally be set to 0. The exception is if the tokenizer supports ** synonyms. In this case see the discussion below for details. *** ** FTS5 assumes the xToken() callback is invoked for each token in the ** order that they occur within the input text. *** ** If an xToken() callback returns any value other than SQLITE_OK, then ** the tokenization should be abandoned and the xTokenize() method should ** immediately return a copy of the xToken() return value. Or, if the ** input buffer is exhausted, xTokenize() should return SQLITE_OK. Finally, ** if an error occurs with the xTokenize() implementation itself, it ** may abandon the tokenization and return any error code other than ** SQLITE_OK or SQLITE_DONE. *** ** SYNONYM SUPPORT *** ** Custom tokenizers may also support synonyms. Consider a case in which a ** user wishes to query for a phrase such as "first place". Using the ** built-in tokenizers, the FTS5 query 'first + place' will match instances ** of "first place" within the document set, but not alternative forms ** such as "1st place". In some applications, it would be better to match ** all instances of "first place" or "1st place" regardless of which form ** the user specified in the MATCH query text. *** ** There are several ways to approach this in FTS5: ** ** By mapping all synonyms to a single token. In this case, the ** In the above example, this means that the tokenizer returns the ** same token for inputs "first" and "1st". Say that token is in ** fact "first", so that when the user inserts the document "I won ** 1st place" entries are added to the index for tokens "1", "won", ** "first" and "place". If the user then queries for '1st + place', ** the tokenizer substitutes "first" for "1st" and the query works ** as expected. ** ** By adding multiple synonyms for a single term to the FTS index. ** In this case, when tokenizing query text, the tokenizer may ** provide multiple synonyms for a single term within the document. ** FTS5 then queries the index for each synonym individually. For ** example, faced with the query: ** ** <codeblock> ** ... MATCH 'first place'</codeblock> ** ** the tokenizer offers both "1st" and "first" as synonyms for the ** first token in the MATCH query and FTS5 effectively runs a query ** similar to: ** ** <codeblock> ** ... MATCH '(first OR 1st) place'</codeblock> ** ** except that, for the purposes of auxiliary functions, the query ** still appears to contain just two phrases - "(first OR 1st)" ** being treated as a single phrase. ** ** By adding multiple synonyms for a single term to the FTS index. ** Using this method, when tokenizing document text, the tokenizer ** provides multiple synonyms for each token. So that when a ** document such as "I won first place" is tokenized, entries are ** added to the FTS index for "i", "won", "first", "1st" and ** "place". ** ** This way, even if the tokenizer does not provide synonyms ** when tokenizing query text (it should not - to do would be ** inefficient), it doesn't matter if the user queries for ** 'first + place' or '1st + place', as there are entries in the ** FTS index corresponding to both forms of the first token. ** *** ** Whether it is parsing document or query text, any call to xToken that ** specifies a <i>tflags</i> argument with the FTS5_TOKEN_COLOCATED bit ** is considered to supply a synonym for the previous token. For example, ** when parsing the document "I won first place", a tokenizer that supports ** synonyms would call xToken() 5 times, as follows: ** ** <codeblock> ** xToken(pCtx, 0, "i", 1, 0, 1); ** xToken(pCtx, 0, "won", 3, 2, 5); ** xToken(pCtx, 0, "first", 5, 6, 11); ** xToken(pCtx, FTS5_TOKEN_COLOCATED, "1st", 3, 6, 11); ** xToken(pCtx, 0, "place", 5, 12, 17); ** </codeblock> ** ** It is an error to specify the FTS5_TOKEN_COLOCATED flag the first time ** xToken() is called. Multiple synonyms may be specified for a single token ** by making multiple calls to xToken(FTS5_TOKEN_COLOCATED) in sequence. ** There is no limit to the number of synonyms that may be provided for a ** single token. ** ** In many cases, method (1) above is the best approach. It does not add ** extra data to the FTS index or require FTS5 to query for multiple terms, ** so it is efficient in terms of disk space and query speed. However, it ** does not support prefix queries very well. If, as suggested above, the ** token "first" is substituted for "1st" by the tokenizer, then the query: ** ** <codeblock> ** ... MATCH '1s'*</codeblock> ** ** will not match documents that contain the token "1st" (as the tokenizer ** will probably not map "1s" to any prefix of "first"). ** ** For full prefix support, method (3) may be preferred. In this case, ** because the index contains entries for both "first" and "1st", prefix ** queries such as 'fi*' or '1s*' will match correctly. However, because ** extra entries are added to the FTS index, this method uses more space ** within the database. ** ** Method (2) offers a midpoint between (1) and (3). Using this method, ** a query such as '1s*' will match documents that contain the literal ** token "1st", but not "first" (assuming the tokenizer is not able to ** provide synonyms for prefixes). However, a non-prefix query like '1st' ** will match against "1st" and "first". This method does not require ** extra disk space, as no extra entries are added to the FTS index. ** On the other hand, it may require more CPU cycles to run MATCH queries, ** as separate queries of the FTS index are required for each synonym. ** ** When using methods (2) or (3), it is important that the tokenizer only ** provide synonyms when tokenizing document text (method (2)) or query ** text (method (3)), not both. Doing so will not cause any errors, but is ** inefficient.

80566. **comment:** ** CAPI3REF: Add A Changeset To A Changegroup *** ** Add all changes within the changeset (or patchset) in buffer pData (size ** nData bytes) to the changegroup. *** ** If the buffer contains a patchset, then all prior calls to this function ** on the same changegroup object must also have specified patchsets. Or, if ** the buffer contains a changeset, so must have the earlier calls to this ** function. Otherwise, SQLITE_ERROR is returned and no changes are added ** to the changegroup. *** ** Rows within the changeset and changegroup are identified by the values in ** their PRIMARY KEY columns. A change in the changeset is considered to ** apply to the same row as a change already present in the changegroup if ** the two rows have the same primary key. *** ** Changes to rows that do not already appear in the changegroup are ** simply copied into it. Or, if both the new changeset and the changegroup ** contain changes that apply to a

single row, the final contents of the ** changegroup depends on the type of each change, as follows:

```
*** <tr><th style="white-space:pre">Existing Change </th> *** <th style="white-space:pre">New Change </th> *** <th>Output Change *** <tr><td>INSERT <td>INSERT <td> ** The new change is ignored. This case does not occur if the new ** changeset was recorded immediately after the changesets already ** added to the changegroup. ** <tr><td>INSERT <td>UPDATE <td> ** The INSERT change remains in the changegroup. The values in the ** INSERT change are modified as if the row was inserted by the ** existing change and then updated according to the new change. ** <tr><td>INSERT <td>DELETE <td> ** The existing INSERT is removed from the changegroup. The DELETE is ** not added. ** <tr><td>UPDATE <td>INSERT <td> ** The new change is ignored. This case does not occur if the new ** changeset was recorded immediately after the changesets already ** added to the changegroup. ** <tr><td>UPDATE <td>UPDATE <td> ** The existing UPDATE remains within the changegroup. It is amended ** so that the accompanying values are as if the row was updated once ** by the existing change and then again by the new change. ** <tr><td>UPDATE <td>DELETE <td> ** The existing UPDATE is replaced by the new DELETE within the ** changegroup. ** <tr><td>DELETE <td>INSERT <td> ** If one or more of the column values in the row inserted by the ** new change differ from those in the row deleted by the existing ** change, the existing DELETE is replaced by an UPDATE within the ** changegroup. Otherwise, if the inserted row is exactly the same ** as the deleted row, the existing DELETE is simply discarded. ** <tr><td>DELETE <td>UPDATE <td> ** The new change is ignored. This case does not occur if the new ** changeset was recorded immediately after the changesets already ** added to the changegroup. ** <tr><td>DELETE <td>DELETE <td> ** The new change is ignored. This case does not occur if the new ** changeset was recorded immediately after the changesets already ** added to the changegroup. ** </table> ***
```

If the new changeset contains changes to a table that is already present ** in the changegroup, then the number of columns and the position of the ** primary key columns for the table must be consistent. If this is not the ** case, this function fails with SQLITE_SCHEMA. If the input changeset ** appears to be corrupt and the corruption is detected, SQLITE_CORRUPT is ** returned. Or, if an out-of-memory condition occurs during processing, this ** function returns SQLITE_NOMEM. In all cases, if an error occurs the ** final contents of the changegroup is undefined. ** * If no error occurs, SQLITE_OK is returned.

80597. ** Structures used by the virtual table interface

80598. **comment:** ** CAPI3REF: Memory Allocation Routines *** An instance of this object defines the interface between SQLite ** and low-level memory allocation routines. *** This object is used in only one place in the SQLite interface. ** A pointer to an instance of this object is the argument to ** [sqlite3_config()] when the configuration option is ** [SQLITE_CONFIG_MALLOC] or [SQLITE_CONFIG_GETMALLOC]. ** By creating an instance of this object ** and passing it to [sqlite3_config()][SQLITE_CONFIG_MALLOC] ** during configuration, an application can specify an alternative ** memory allocation subsystem for SQLite to use for all of its ** dynamic memory needs. *** Note that SQLite comes with several [built-in memory allocators] ** that are perfectly adequate for the overwhelming majority of applications ** and that this object is only useful to a tiny minority of applications ** with specialized memory allocation requirements. This object is ** also used during testing of SQLite in order to specify an alternative ** memory allocator that simulates memory out-of-memory conditions in ** order to verify that SQLite recovers gracefully from such ** conditions. *** The xMalloc, xRealloc, and xFree methods must work like the ** malloc(), realloc() and free() functions from the standard C library. ** ^SQLite guarantees that the second argument to ** xRealloc is always a value returned by a prior call to xRoundup. ** ^xSize should return the allocated size of a memory allocation ** previously obtained from xMalloc or xRealloc. The allocated size ** is always at least as big as the requested size but may be larger. ** ^The xRoundup method returns what would be the allocated size of ** a memory allocation given a particular requested size. Most memory ** allocators round up memory allocations at least to the next multiple ** of 8. Some allocators round up to a larger multiple or to a power of 2. ** Every memory allocation request coming in through [sqlite3_malloc()] ** or [sqlite3_realloc()] first calls xRoundup. If xRoundup returns 0, ** that causes the corresponding memory allocation to fail. ** ^The xInit method initializes the memory allocator. For example, ** it might allocate any required mutexes or initialize internal data ** structures. The xShutdown method is invoked (indirectly) by ** [sqlite3_shutdown()] and should deallocate any resources acquired ** by xInit. The pAppData pointer is used as the only parameter to ** xInit and xShutdown. ** ^SQLite holds the [SQLITE_MUTEX_STATIC_MASTER] mutex when it invokes ** the xInit method, so the xInit method need not be threadsafe. The ** xShutdown method is only called from [sqlite3_shutdown()] so it does ** not need to be threadsafe either. For all other methods, SQLite ** holds the [SQLITE_MUTEX_STATIC_MEM] mutex as long as the ** [SQLITE_CONFIG_MEMSTATUS] configuration option is turned on (which ** it is by default) and so the methods are automatically serialized. ** However, if [SQLITE_CONFIG_MEMSTATUS] is disabled, then the other ** methods must be threadsafe or else make their own arrangements for ** serialization. ** ^SQLite will never invoke xInit() more than once without an intervening ** call to xShutdown().

80601. ** CAPI3REF: A Handle To An Open BLOB ** KEYWORDS: {BLOB handle} {BLOB handles} *** An instance of this object represents an open BLOB on which ** [sqlite3_blob_open | incremental BLOB I/O] can be performed. ** ^Objects of this type are created by [sqlite3_blob_open()] ** and destroyed by

[sqlite3_blob_close()]. ** ^The [sqlite3_blob_read()] and [sqlite3_blob_write()] interfaces ** can be used to read or write small subsections of the BLOB. ** ^The [sqlite3_blob_bytes()] interface returns the size of the BLOB in bytes.

80602. ** CAPI3REF: Retrieving Statement SQL ** METHOD: sqlite3_stmt ** ** ^The sqlite3_sql(P) interface returns a pointer to a copy of the UTF-8 ** SQL text used to create [prepared statement] P if P was ** created by [sqlite3_prepare_v2()], [sqlite3_prepare_v3()], ** [sqlite3_prepare16_v2()], or [sqlite3_prepare16_v3()]. ** ^The sqlite3_expanded_sql(P) interface returns a pointer to a UTF-8 ** string containing the SQL text of prepared statement P with ** [bound parameters] expanded. ** ** ^For example, if a prepared statement is created using the SQL ** text "SELECT \$abc,:xyz" and if parameter \$abc is bound to integer 2345 ** and parameter :xyz is unbound, then sqlite3_sql() will return ** the original string, "SELECT \$abc,:xyz" but sqlite3_expanded_sql() ** will return "SELECT 2345,NULL".) ** ** ^The sqlite3_expanded_sql() interface returns NULL if insufficient memory ** is available to hold the result, or if the result would exceed the ** the maximum string length determined by the [SQLITE_LIMIT_LENGTH]. ** ** ^The [SQLITE_TRACE_SIZE_LIMIT] compile-time option limits the size of ** bound parameter expansions. ^The [SQLITE_OMIT_TRACE] compile-time ** option causes sqlite3_expanded_sql() to always return NULL. ** ** ^The string returned by sqlite3_sql(P) is managed by SQLite and is ** automatically freed when the prepared statement is finalized. ** ^The string returned by sqlite3_expanded_sql(P), on the other hand, ** is obtained from [sqlite3_malloc()] and must be free by the application ** by passing it to [sqlite3_free()].

80603. ** Specify the activation key for a CEROD database. Unless ** activated, none of the CEROD routines will work.

80604. ** CAPI3REF: Run-time Limits ** METHOD: sqlite3 ** ** ^This interface allows the size of various constructs to be limited ** on a connection by connection basis. The first parameter is the ** [database connection] whose limit is to be set or queried. The ** second parameter is one of the [limit categories] that define a ** class of constructs to be size limited. The third parameter is the ** new limit for that construct. ^If the new limit is a negative number, the limit is unchanged. ** ^For each limit category SQLITE_LIMIT_<i>NAME</i> there is a ** [limits | hard upper bound] ** set at compile-time by a C preprocessor macro called ** [limits | SQLITE_MAX_<i>NAME</i>]. ** ^The "_LIMIT_" in the name is changed to "_MAX_").) ** ** ^Attempts to increase a limit above its hard upper bound are ** silently truncated to the hard upper bound. ** ** ^Regardless of whether or not the limit was changed, the ** [sqlite3_limit()] interface returns the prior value of the limit. ** ^Hence, to find the current value of a limit without changing it, ** simply invoke this interface with the third parameter set to -1. ** ** Run-time limits are intended for use in applications that manage ** both their own internal database and also databases that are controlled ** by untrusted external sources. An example application might be a ** web browser that has its own databases for storing history and ** separate databases controlled by JavaScript applications downloaded ** off the Internet. The internal databases can be given the ** large, default limits. Databases managed by external sources can ** be given much smaller limits designed to prevent a denial of service ** attack. Developers might also want to use the [sqlite3_set_authorizer()] ** interface to further control untrusted SQL. The size of the database ** created by an untrusted script can be contained using the ** [max_page_count] [PRAGMA]. ** ** New run-time limit categories may be added in future releases.

80605. ** CAPI3REF: Load The Difference Between Tables Into A Session ** ** If it is not already attached to the session object passed as the first ** argument, this function attaches table zTbl in the same manner as the ** [sqlite3session_attach()] function. If zTbl does not exist, or if it ** does not have a primary key, this function is a no-op (but does not return ** an error). ** ** Argument zFromDb must be the name of a database ("main", "temp" etc.) ** attached to the same database handle as the session object that contains ** a table compatible with the table attached to the session by this function. ** A table is considered compatible if it: *** ** Has the same set of columns declared in the same order, and ** Has the same PRIMARY KEY definition. ** ** ** If the tables are not compatible, SQLITE_SCHEMA is returned. If the tables ** are compatible but do not have any PRIMARY KEY columns, it is not an error ** but no changes are added to the session object. As with other session ** APIs, tables without PRIMARY KEYS are simply ignored. ** ** This function adds a set of changes to the session object that could be ** used to update the table in database zFrom (call this the "from-table") ** so that its content is the same as the table attached to the session ** object (call this the "to-table"). Specifically: *** ** For each row (primary key) that exists in the to-table but not in ** the from-table, an INSERT record is added to the session object. ** ** For each row (primary key) that exists in the to-table but not in ** the from-table, a DELETE record is added to the session object. ** ** For each row (primary key) that exists in both tables, but features ** different non-PK values in each, an UPDATE record is added to the ** session. ** ** ** To clarify, if this function is called and then a changeset constructed ** using [sqlite3session_changeset()], then after applying that changeset to ** database zFrom the contents of the two compatible tables would be ** identical. ** ** It an error if database zFrom does not exist or does not contain the ** required compatible table. ** ** If the operation successful, SQLITE_OK is returned. Otherwise, an SQLite ** error code. In this case, if argument pzErrMsg is not NULL, *pzErrMsg ** may be set to point to a buffer containing an English language error ** message. It is the responsibility of the caller to free this buffer using ** sqlite3_free().

80606. Trigger Name Table Name

80607. comment: previously SQLITE_CONFIG_CHUNKALLOC 12 which is now unused.

label: code-design

80608. The database file is locked

80609. OUT: New session object

80610. The methods above are in version 1 of the sqlite_module object. Those ** below are for version 2 and greater.

80611. ** CAPI3REF: Create An Iterator To Traverse A Changeset ** ** Create an iterator used to iterate through the contents of a changeset. ** If successful, *pp is set to point to the iterator handle and SQLITE_OK ** is returned. Otherwise, if an error occurs, *pp is set to zero and an ** SQLite error code is returned. ** ** The following functions can be used to advance and query a changeset ** iterator created by this function: *** ** [sqlite3changeset_next()] ** [sqlite3changeset_op()] ** [sqlite3changeset_new()] ** [sqlite3changeset_old()] ** ** ** It is the responsibility of the caller to eventually destroy the iterator ** by passing it to [sqlite3changeset_finalize()]. The buffer containing the ** changeset (pChangeset) must remain valid until after the iterator is ** destroyed. ** ** Assuming the changeset blob was created by one of the ** [sqlite3session_changeset()], [sqlite3changeset_concat()] or ** [sqlite3changeset_invert()] functions, all changes within the changeset ** that apply to a single table are grouped together. This means that when ** an application iterates through a changeset using an iterator created by ** this function, all changes that relate to a single table are visited ** consecutively. There is no chance that the iterator will visit a change ** the applies to table X, then one for table Y, and then later on visit ** another change for table X.

80612. Copy of third arg to _filter_table()

80613. ** CAPI3REF: Error Codes And Messages ** METHOD: sqlite3 ** ** ^If the most recent sqlite3_* API call associated with ** [database connection] D failed, then the sqlite3_errcode(D) interface ** returns the numeric [result code] or [extended result code] for that ** API call. ** If the most recent API call was successful, ** then the return value from sqlite3_errcode() is undefined. ** ^The sqlite3_extended_errcode() ** interface is the same except that it always returns the ** [extended result code] even when extended result codes are ** disabled. ** ** ^The sqlite3_errmsg() and sqlite3_errmsg16() return English-language ** text that describes the error, as either UTF-8 or UTF-16 respectively. ** ^Memory to hold the error message string is managed internally. ** The application does not need to worry about freeing the result. ** However, the error string might be overwritten or deallocated by ** subsequent calls to other SQLite interface functions. ** ** ^The sqlite3_errstr() interface returns the English-language text ** that describes the [result code], as UTF-8. ** ^Memory to hold the error message string is managed internally ** and must not be freed by the application). ** ** When the serialized [threading mode] is in use, it might be the ** case that a second error occurs on a separate thread in between ** the time of the first error and the call to these interfaces. ** When that happens, the second error will be reported since these ** interfaces always report the most recent result. To avoid ** this, each thread can obtain exclusive use of the [database connection] D ** by invoking [sqlite3_mutex_enter]([sqlite3_db_mutex](D)) before beginning ** to use D and invoking [sqlite3_mutex_leave]([sqlite3_db_mutex](D)) after ** all calls to the interfaces listed here are completed. ** ** If an interface fails with SQLITE_MISUSE, that means the interface ** was invoked incorrectly by the application. In that case, the ** error code and message may or may not be set.

80614. String or BLOB exceeds size limit

80615. ** CAPI3REF: Data Change Notification Callbacks ** METHOD: sqlite3 ** ** ^The sqlite3_update_hook() interface registers a callback function ** with the [database connection] identified by the first argument ** to be invoked whenever a row is updated, inserted or deleted in ** a [rowid table]. ** ^Any callback set by a previous call to this function ** for the same database connection is overridden. ** ** ^The second argument is a pointer to the function to invoke when a ** row is updated, inserted or deleted in a rowid table. ** ^The first argument to the callback is a copy of the third argument ** to sqlite3_update_hook(). ** ^The second callback argument is one of [SQLITE_INSERT], [SQLITE_DELETE], ** or [SQLITE_UPDATE], depending on the operation that caused the callback ** to be invoked. ** ^The third and fourth arguments to the callback contain pointers to the ** database and table name containing the affected row. ** ^The final callback parameter is the [rowid] of the row. ** ^In the case of an update, this is the [rowid] after the update takes place. ** ** ^The update hook is not invoked when internal system tables are ** modified (i.e. sqlite_master and sqlite_sequence).) ** ** ^The update hook is not invoked when [WITHOUT ROWID] tables are modified. ** ** ^In the current implementation, the update hook ** is not invoked when conflicting rows are deleted because of an ** [ON CONFLICT | ON CONFLICT REPLACE] clause. ^Nor is the update hook ** invoked when rows are deleted using the [truncate optimization]. ** The exceptions defined in this paragraph might change in a future ** release of SQLite. ** ** The update hook implementation must not do anything that will modify ** the database connection that invoked the update hook. Any actions ** to modify the database connection must be deferred until after the ** completion of the [sqlite3_step()] call that triggered the update hook. ** Note that [sqlite3_prepare_v2()] and [sqlite3_step()] both modify their ** database connections for the meaning of "modify" in this paragraph. ** ** ^The sqlite3_update_hook(D,C,P) function ** returns the P argument from the previous call ** on the same [database connection] D, or NULL for ** the first call on D. ** ** See also the [sqlite3_commit_hook()], [sqlite3_rollback_hook()], ** and [sqlite3_prepupdate_hook()] interfaces.

80619. ** CAPI3REF: 64-Bit Integer Types ** KEYWORDS: sqlite_int64 sqlite_uint64 *** ** Because there is no cross-platform way to specify 64-bit integer types ** SQLite includes typedefs for 64-bit signed and unsigned integers. ** ** The sqlite3_int64 and sqlite3_uint64 are the preferred type definitions. ** The sqlite_int64 and sqlite_uint64 types are supported for backwards ** compatibility only. ** ** ^The sqlite3_int64 and sqlite_int64 types can store integer values ** between -9223372036854775808 and +9223372036854775807 inclusive. ^The ** sqlite3_uint64 and sqlite_uint64 types can store integer values ** between 0 and +18446744073709551615 inclusive.

80620. ** CAPI3REF: Prepare Flags ** ** These constants define various flags that can be passed into ** "prepFlags" parameter of the [sqlite3_prepare_v3()] and ** [sqlite3_prepare16_v3()] interfaces. ** ** New flags may be added in future releases of SQLite. ** ** <dl> ** [[SQLITE_PREPARE_PERSISTENT]]
^(<dt>SQLITE_PREPARE_PERSISTENT</dt> ** <dd>The SQLITE_PREPARE_PERSISTENT flag is a hint to the query planner ** that the prepared statement will be retained for a long time and ** probably reused many times.)^ ^Without this flag, [sqlite3_prepare_v3()] ** and [sqlite3_prepare16_v3()] assume that the prepared statement will ** be used just once or at most a few times and then destroyed using ** [sqlite3_finalize()] relatively soon. The current implementation acts ** on this hint by avoiding the use of [lookaside memory] so as not to ** deplete the limited store of lookaside memory. Future versions of ** SQLite may act on this hint differently. ** </dl>

80621. Wait for writers, then checkpoint

80622. ** CAPI3REF: Opening A New Database Connection ** CONSTRUCTOR: sqlite3 *** ** ^These routines open an SQLite database file as specified by the ** filename argument. ^The filename argument is interpreted as UTF-8 for ** sqlite3_open() and sqlite3_open_v2() and as UTF-16 in the native byte ** order for sqlite3_open16(). ^A [database connection] handle is usually ** returned in *ppDb, even if an error occurs. The only exception is that ** if SQLite is unable to allocate memory to hold the [sqlite3] object, ** a NULL will be written into *ppDb instead of a pointer to the [sqlite3] ** object.^ ^If the database is opened (and/or created) successfully, then ** [SQLITE_OK] is returned. Otherwise an [error code] is returned.)^ ^The ** [sqlite3_errmsg0()] or [sqlite3_errmsg160()] routines can be used to obtain ** an English language description of the error following a failure of any ** of the sqlite3_open() routines. *** ** ^The default encoding will be UTF-8 for databases created using ** sqlite3_open() or sqlite3_open_v2(). ^The default encoding for databases ** created using sqlite3_open16() will be UTF-16 in the native byte order. *** ** Whether or not an error occurs when it is opened, resources ** associated with the [database connection] handle should be released by ** passing it to [sqlite3_close()] when it is no longer required. *** ** The sqlite3_open_v2() interface works like sqlite3_open() ** except that it accepts two additional parameters for additional control ** over the new database connection. ^The flags parameter to ** sqlite3_open_v2() can take one of ** the following three values, optionally combined with the ** [SQLITE_OPEN_NOMUTEX], [SQLITE_OPEN_FULLMUTEX], [SQLITE_OPEN_SHARED_CACHE], ** [SQLITE_OPEN_PRIVATECACHE], and/or [SQLITE_OPEN_URI] flags:)*** ** <dl> ** (<dt>[SQLITE_OPEN_READONLY]</dt> ** <dd>The database is opened in read-only mode. If the database does not ** already exist, an error is returned.</dd>)*** ** ^(<dt>[SQLITE_OPEN_READWRITE]</dt> ** <dd>The database is opened for reading and writing if possible, or reading ** only if the file is write protected by the operating system. In either ** case the database must already exist, otherwise an error is returned.</dd>)*** ** ^(<dt>[SQLITE_OPEN_READWRITE] | [SQLITE_OPEN_CREATE]</dt> ** <dd>The database is opened for reading and writing, and is created if ** it does not already exist. This is the behavior that is always used for ** sqlite3_open() and sqlite3_open16().</dd>)*** ** <dd> If the 3rd parameter to sqlite3_open_v2() is not one of the ** combinations shown above optionally combined with other ** [SQLITE_OPEN_READONLY | SQLITE_OPEN_* bits] ** then the behavior is undefined. *** ** ^If the [SQLITE_OPEN_NOMUTEX] flag is set, then the database connection ** opens in the multi-thread [threading mode] as long as the single-thread ** mode has not been set at compile-time or start-time. ^If the ** [SQLITE_OPEN_FULLMUTEX] flag is set then the database connection opens ** in the serialized [threading mode] unless single-thread was ** previously selected at compile-time or start-time. ** ^The [SQLITE_OPEN_SHARED_CACHE] flag causes the database connection to be ** eligible to use [shared cache mode], regardless of whether or not shared ** cache is enabled using [sqlite3_enable_shared_cache()]. ^The ** [SQLITE_OPEN_PRIVATECACHE] flag causes the database connection to not ** participate in [shared cache mode] even if it is enabled. *** ** ^The fourth parameter to sqlite3_open_v2() is the name of the ** [sqlite3_vfs] object that defines the operating system interface that ** the new database connection should use. ^If the fourth parameter is ** a NULL pointer then the default [sqlite3_vfs] object is used. *** ** ^If the filename is ":memory:", then a private, temporary in-memory database ** is created for the connection. ^This in-memory database will vanish when ** the database connection is closed. Future versions of SQLite might ** make use of additional special filenames that begin with the ":" character. ** It is recommended that when a database filename actually does begin with ** a ":" character you should prefix the filename with a pathname such as ** "/" to avoid ambiguity. *** ** ^If the filename is an empty string, then a private, temporary ** on-disk database will be created. ^This private database will be ** automatically deleted as soon as the database connection is closed. *** ** [[URI filenames in sqlite3_open()]] <h3>URI Filenames</h3> *** ** ^If [URI filename] interpretation is enabled, and the filename argument ** begins with "file:", then the filename is interpreted as a URI. ^URI ** filename interpretation is enabled if the [SQLITE_OPEN_URI] flag is ** set in the fourth argument to sqlite3_open_v2(), or if it has ** been enabled globally using the [SQLITE_CONFIG_URI] option with the ** [sqlite3_config0()] method or by the [SQLITE_USE_URI] compile-time option. ** As of SQLite version 3.7.7, URI filename interpretation is turned off ** by default, but future releases of SQLite might enable URI filename ** interpretation by default. See "[URI filenames]" for additional ** information. *** ** URI filenames are parsed according to RFC 3986. ^If the URI contains an ** authority, then it must be either an empty string or the string ** "localhost". ^If the authority is not an empty string or "localhost", an ** error is returned to the caller. ^The fragment component of a URI, if ** present, is ignored. *** ** ^SQLite uses the path component of the URI as the name of the disk file ** which contains the database. ^If the path begins with a '/' character, ** then it is interpreted as an absolute path. ^If the path does not begin ** with a '/' (meaning that the authority section is omitted from the URI) ** then the path is interpreted as a relative path. ** ^On windows, the first component of an absolute path ** is a drive specification (e.g. "C:").*** ** [[core URI query parameters]] ** The query component of a URI may contain parameters that are interpreted ** either by SQLite itself, or by a [VFS | custom VFS implementation]. ** SQLite and its built-in [VFSes] interpret the ** following query parameters: *** ** ** vfs: ^The "vfs" parameter may be used to specify the name of ** a VFS object that provides the operating system interface that should ** be used to access the database file on disk. ^If this option is set to ** an empty string the default VFS object is used. ^Specifying an unknown ** VFS is an error. ^If sqlite3_open_v2() is used and the vfs option is ** present, then the VFS specified by the option takes precedence over ** the value passed as the fourth parameter to sqlite3_open_v2(). *** ** mode: ^The mode parameter may be set to either "ro", "rw", ** "rwc", or "memory". Attempting to set it to any other value is ** an error). ** ^If "ro" is specified, then the database is opened for read-only ** access, just as if the [SQLITE_OPEN_READONLY] flag had been set in the ** third argument to sqlite3_open_v2(). ^If the mode option is set to ** "rw", then the database is opened for read-write (but not create) ** access, as if SQLITE_OPEN_READWRITE (but not SQLITE_OPEN_CREATE) had ** been set. ^Value "rwc" is equivalent to setting both ** SQLITE_OPEN_READWRITE and SQLITE_OPEN_CREATE. ^If the mode option is ** set to "memory" then a pure [in-memory database] that never reads ** or writes from disk is used. ^It is an error to specify a value for ** the mode parameter that is less restrictive than that specified by ** the flags passed in the third parameter to sqlite3_open_v2(). *** ** cache: ^The cache parameter may be set to either "shared" or ** "private". ^Setting it to "shared" is equivalent to setting the ** SQLITE_OPEN_SHARED_CACHE bit in the flags argument passed to ** sqlite3_open_v2(). ^Setting the cache parameter to "private" is ** equivalent to setting the SQLITE_OPEN_PRIVATECACHE bit. ** ^If sqlite3_open_v2() is used and the "cache" parameter is present in ** a URI filename, its value overrides any behavior requested by setting ** SQLITE_OPEN_PRIVATECACHE or SQLITE_OPEN_SHARED_CACHE flag. *** ** psow: ^The psow parameter indicates whether or not the ** [powersafe overwrite] property does or does not apply to the ** storage media on which the database file resides. *** ** nolock: ^The nolock parameter is a boolean query parameter ** which if set disables file locking in rollback journal modes. This ** is useful for accessing a database on a filesystem that does not ** support locking. Caution: Database corruption might result if two ** or more processes write to the same database and any one of those ** processes uses nolock=1. *** ** immutable: ^The immutable parameter is a boolean query ** parameter that indicates that the database file is stored on ** read-only media. ^When immutable is set, SQLite assumes that the ** database file cannot be changed, even by a process with higher ** privilege, and so the database is opened read-only and all locking ** and change detection is disabled. Caution: Setting the immutable ** property on a database file that does in fact change can result ** in incorrect query results and/or [SQLITE_CORRUPT] errors. ** See also: [SQLITE_IOCAP_IMMUTABLE]. *** ** ** ^Specifying an unknown parameter in the query component of a URI is not an ** error. Future versions of SQLite might understand additional query ** parameters. See "[query parameters with special meaning to SQLite]" for ** additional information. *** ** [[URI filename examples]] <h3>URI filename examples</h3> *** ** <table border="1" align="center" cellpadding="5"> ** <tr><th> URI filenames </th> Results </tr><td> file:data.db <td> ** Open the file "data.db" in the current directory. ** <tr><td> file:/home/fred/data.db
 ** file:///home/fred/data.db
 ** file://localhost/home/fred/data.db
 <td> ** Open the database file "/home/fred/data.db". ** <tr><td> file://darkstar/home/fred/data.db <td> ** An error. "darkstar" is not a recognized authority. ** <tr><td style="white-space:nowrap"> ** file:///C:/Documents%20and%20Settings/fred/Desktop/data.db ** <td> Windows only: Open the file "data.db" on fred's desktop on drive ** C:. Note that the %20 escaping in this example is not strictly ** necessary - space characters can be used literally ** in URI filenames. ** <tr><td> file:data.db?mode=ro&cache=private <td> ** Open file "data.db" in the current directory for read-only access. ** Regardless of whether or not shared-cache mode is enabled by ** default, use a private cache. ** <tr><td> file:/home/fred/data.db?vfs=unix-dotfile

<td> ** Open file "/home/fred/data.db". Use the special VFS "unix-dotfile" ** that uses dot-files in place of posix advisory locking. ** <tr><td> file:data.db? mode=readonly <td> ** An error. "readonly" is not a valid option for the "mode" parameter. ** </table> ** ** ^URI hexadecimal escape sequences (%HH) are supported within the path and ** query components of a URI. A hexadecimal escape sequence consists of a ** percent sign - "%" - followed by exactly two hexadecimal digits ** specifying an octet value. ^Before the path or query components of a ** URI filename are interpreted, they are encoded using UTF-8 and all ** hexadecimal escape sequences replaced by a single byte containing the ** corresponding octet. If this process generates an invalid UTF-8 encoding, ** the results are undefined. ** ** Note to Windows users: The encoding used for the filename argument ** of sqlite3_open() and sqlite3_open_v2() must be UTF-8, not whatever ** codepage is currently defined. Filenames containing international ** characters must be converted to UTF-8 prior to passing them into ** sqlite3_open() or sqlite3_open_v2(). ** ** Note to Windows Runtime users: The temporary directory must be set ** prior to calling sqlite3_open() or sqlite3_open_v2(). Otherwise, various ** features that require the use of temporary files may fail. ** ** See also: [sqlite3_temp_directory]

80623. ** CAPI3REF: Run-Time Limit Categories ** KEYWORDS: {limit category} {*limit categories} ** ** These constants define various performance limits ** that can be lowered at run-time using [sqlite3_limit()]. ** The synopsis of the meanings of the various limits is shown below. ** Additional information is available at [limits | Limits in SQLite]. ** ** <dl> ** [[SQLITE_LIMIT_LENGTH]] ^<dt>SQLITE_LIMIT_LENGTH</dt> ** <dd>The maximum size of any string or BLOB or table row, in bytes.<dd>^ ** [[SQLITE_LIMIT_SQL_LENGTH]] ^<dt>SQLITE_LIMIT_SQL_LENGTH</dt> ** <dd>The maximum length of an SQL statement, in bytes.<dd>^ ** [[SQLITE_LIMIT_COLUMN]] ^<dt>SQLITE_LIMIT_COLUMN</dt> ** <dd>The maximum number of columns in a table definition or in the ** result set of a [SELECT] or the maximum number of columns in an index ** or in an ORDER BY or GROUP BY clause.<dd>^ ** [[SQLITE_LIMIT_EXPR_DEPTH]] ^<dt>SQLITE_LIMIT_EXPR_DEPTH</dt> ** <dd>The maximum depth of the parse tree on any expression.<dd>^ ** [[SQLITE_LIMIT_COMPOUND_SELECT]] ^<dt>SQLITE_LIMIT_COMPOUND_SELECT</dt> ** <dd>The maximum number of terms in a compound SELECT statement.<dd>^ ** [[SQLITE_LIMIT_VDBE_OP]] ^<dt>SQLITE_LIMIT_VDBE_OP</dt> ** <dd>The maximum number of instructions in a virtual machine program ** used to implement an SQL statement. - label:** code-design
80685. **comment:** ** CAPI3REF: Apply A Changeset To A Database ** Apply a changeset to a database. This function attempts to update the ** "main" database attached to handle db with the changes found in the ** changeset passed via the second and third arguments. *** The fourth argument (xFilter) passed to this function is the "filter ** callback". If it is not NULL, then for each table affected by at least one ** change in the changeset, the filter callback is invoked with ** the table name as the second argument, and a copy of the context pointer ** passed as the sixth argument to this function as the first. If the "filter ** callback" returns zero, then no attempt is made to apply any changes to ** the table. Otherwise, if the return value is non-zero or the xFilter ** argument to this function is NULL, all changes related to the table are ** attempted. *** For each table that is not excluded by the filter callback, this function ** tests that the target database contains a compatible table. A table is ** considered compatible if all of the following are true: *** ** The table has the same name as the name recorded in the ** changeset, and ** The table has at least as many columns as recorded in the ** changeset, and ** The table has primary key columns in the same position as ** recorded in the changeset. ** *** If there is no compatible table, it is not an error, but none of the ** changes associated with the table are applied. A warning message is issued ** via the sqlite3_log() mechanism with the error code SQLITE_SCHEMA. At most ** one such warning is issued for each table in the changeset. *** For each change for which there is a compatible table, an attempt is made ** to modify the table contents according to the UPDATE, INSERT or DELETE ** change. If a change cannot be applied cleanly, the conflict handler ** function passed as the fifth argument to sqlite3changeset_apply() may be ** invoked. A description of exactly when the conflict handler is invoked for ** each type of change is below. *** Unlike the xFilter argument, xConflict may not be passed NULL. The results ** of passing anything other than a valid function pointer as the xConflict ** argument are undefined. *** Each time the conflict handler function is invoked, it must return one ** of [SQLITE_CHANGESET OMIT], [SQLITE_CHANGESET_ABORT] or ** [SQLITE_CHANGESET_REPLACE]. SQLITE_CHANGESET_REPLACE may only be returned ** if the second argument passed to the conflict handler is either ** SQLITE_CHANGESET_DATA or SQLITE_CHANGESET_CONFLICT. If the conflict-handler ** returns an illegal value, any changes already made are rolled back and ** the call to sqlite3changeset_apply() returns SQLITE_MISUSE. Different ** actions are taken by sqlite3changeset_apply() depending on the value ** returned by each invocation of the conflict-handler function. Refer to ** the documentation for the three ** [SQLITE_CHANGESET OMIT]available return values] for details. *** <dl> ** <dt>DELETE Changes<dd> ** For each DELETE change, this function checks if the target database ** contains a row with the same primary key value (or values) as the ** original row values stored in the changeset. If it does, and the values ** stored in all non-primary key columns also match the values stored in ** the changeset the row is deleted from the target database. *** If a row with matching primary key values is found, but one or more of ** the non-primary key fields contains a value different from the original ** row value stored in the changeset, the conflict-handler function is ** invoked with [SQLITE_CHANGESET DATA] as the second argument. If the ** database table has more columns than are recorded in the changeset, ** only the values of those non-primary key fields are compared against ** the current database contents - any trailing database

table columns ** are ignored. *** If no row with matching primary key values is found in the database, ** the conflict-handler function is invoked with [SQLITE_CHANGESET_NOTFOUND] ** passed as the second argument. *** If the DELETE operation is attempted, but SQLite returns SQLITE_CONSTRAINT ** (which can only happen if a foreign key constraint is violated), the ** conflict-handler function is invoked with [SQLITE_CHANGESET_CONSTRAINT] ** passed as the second argument. This includes the case where the DELETE ** operation is attempted because an earlier call to the conflict handler ** function returned [SQLITE_CHANGESET_REPLACE]. *** <dt>INSERT Changes<dd> ** For each INSERT change, an attempt is made to insert the new row into ** the database. If the changeset row contains fewer fields than the ** database table, the trailing fields are populated with their default ** values. *** If the attempt to insert the row fails because the database already ** contains a row with the same primary key values, the conflict handler ** function is invoked with the second argument set to ** [SQLITE_CHANGESET_CONFLICT]. *** If the attempt to insert the row fails because of some other constraint ** violation (e.g. NOT NULL or UNIQUE), the conflict handler function is ** invoked with the second argument set to [SQLITE_CHANGESET_CONSTRAINT]. ** This includes the case where the INSERT operation is re-attempted because ** an earlier call to the conflict handler function returned ** [SQLITE_CHANGESET_REPLACE]. *** <dt>UPDATE Changes<dd> ** For each UPDATE change, this function checks if the target database ** contains a row with the same primary key value (or values) as the ** original row values stored in the changeset. If it does, and the values ** stored in all modified non-primary key columns also match the values ** stored in the changeset the row is updated within the target database. *** If a row with matching primary key values is found, but one or more of ** the modified non-primary key fields contains a value different from an ** original row value stored in the changeset, the conflict-handler function ** is invoked with [SQLITE_CHANGESET_DATA] as the second argument. Since ** UPDATE changes only contain values for non-primary key fields that are ** to be modified, only those fields need to match the original values to ** avoid the SQLITE_CHANGESET_DATA conflict-handler callback. *** If no row with matching primary key values is found in the database, ** the conflict-handler function is invoked with [SQLITE_CHANGESET_NOTFOUND] ** passed as the second argument. *** If the UPDATE operation is attempted, but SQLite returns ** SQLITE_CONSTRAINT, the conflict-handler function is invoked with ** [SQLITE_CHANGESET_CONSTRAINT] passed as the second argument. ** This includes the case where the UPDATE operation is attempted after ** an earlier call to the conflict handler function returned ** [SQLITE_CHANGESET_REPLACE]. ** </dt> ** It is safe to execute SQL statements, including those that write to the ** table that the callback related to, from within the xConflict callback. ** This can be used to further customize the applications conflict ** resolution strategy. *** All changes made by this function are enclosed in a savepoint transaction. ** If any other error (aside from a constraint failure when attempting to ** write to the target database) occurs, then the savepoint transaction is ** rolled back, restoring the target database to its original state, and an ** SQLite error code returned.

80686. **comment:** ** CAPI3REF: Formatted String Printing Functions *** These routines are work-alikes of the "printf()" family of functions ** from the standard C library. ** These routines understand most of the common K&R formatting options, ** plus some additional non-standard formats, detailed below. ** Note that some of the more obscure formatting options from recent ** C-library standards are omitted from this implementation. *** ^The sqlite3_mprintf() and sqlite3_vmpfint() routines write their ** results into memory obtained from [sqlite3_malloc0]. ** The strings returned by these two routines should be ** released by [sqlite3_free0]. ^Both routines return a ** NULL pointer if [sqlite3_malloc0] is unable to allocate enough ** memory to hold the resulting string. ** *** ^The sqlite3_snprintf() routine is similar to "snprintf()" from ** the standard C library. The result is written into the ** buffer supplied as the second parameter whose size is given by ** the first parameter. Note that the order of the ** first two parameters is reversed from snprintf().)^ This is an ** historical accident that cannot be fixed without breaking ** backwards compatibility. ^Note also that sqlite3_snprintf() ** returns a pointer to its buffer instead of the number of ** characters actually written into the buffer.)^ We admit that ** the number of characters written would be a more useful return ** value but we cannot change the implementation of sqlite3_snprintf() ** now without breaking compatibility. *** ^As long as the buffer size is greater than zero, sqlite3_snprintf() ** guarantees that the buffer is always zero-terminated. ^The first ** parameter "n" is the total size of the buffer, including space for ** the zero terminator. So the longest string that can be completely ** written will be n-1 characters. *** ^The sqlite3_vsprintf() routine is a varargs version of sqlite3_snprintf(). *** These routines all implement some additional formatting ** options that are useful for constructing SQL statements. ** All of the usual printf() formatting options apply. In addition, there ** is are "%q", "%Q", "%w" and "%z" options. *** ^The %q option works like %s in that it substitutes a nul-terminated ** string from the argument list. But %q also doubles every \" character. ** %q is designed for use inside a string literal.)^ By doubling each \" ** character it escapes that character and allows it to be inserted into ** the string. *** For example, assume the string variable zText contains text as follows: *** <blockquote><pre> ** char *zText = "It's a happy day!"; ** </pre></blockquote> *** One can use this text in an SQL statement as follows: *** <blockquote><pre> ** char *zSQL = sqlite3_mprintf("INSERT INTO table VALUES(%q)", zText); ** sqlite3_exec(db, zSQL, 0, 0, 0); ** sqlite3_free(zSQL); ** </pre></blockquote> *** Because the %q format string is used, the \" character in zText ** is escaped and the SQL generated is as follows: *** <blockquote><pre> ** INSERT INTO table1 VALUES('It's a happy day!') ** </pre></blockquote> *** This is correct. Had we used %s instead of %q, the generated SQL ** would have looked like this: ** *** <blockquote><pre> ** INSERT INTO table1 VALUES('It's a happy day!'); ** </pre></blockquote> *** This second example is an SQL syntax error. As a general rule you should ** always use %q instead of %s when inserting text into a string literal. *** ^The %Q option works like %q except it also adds single quotes around ** the outside of the total string. Additionally, if the parameter in the ** argument list is a NULL pointer, %Q substitutes the text "NULL" (without ** single quotes).)^ So, for example, one could say: *** <blockquote><pre> ** char *zSQL = sqlite3_mprintf("INSERT INTO table VALUES(%Q)", zText); ** sqlite3_exec(db, zSQL, 0, 0, 0); ** sqlite3_free(zSQL); ** </pre></blockquote> *** The code above will render a correct SQL statement in the zSQL ** variable even if the zText variable is a NULL pointer. *** ^The "%w" formatting option is like "%q" except that it expects to ** be contained within double-quotes instead of single quotes, and it ** escapes the double-quote character instead of the single-quote ** character.)^ The "%w" formatting option is intended for safely inserting ** table and column names into a constructed SQL statement. *** ^The "%z" formatting option works like "%s" but with the ** addition that after the string has been read and copied into ** the result, [sqlite3_free0] is called on the input string.)^

80687. ** CAPI3REF: Fundamental Datatypes ** KEYWORDS: SQLITE_TEXT *** ^Every value in SQLite has one of five fundamental datatypes: *** ** 64-bit signed integer ** 64-bit IEEE floating point number ** string ** BLOB ** NULL **)^ *** These constants are codes for each of those types. *** Note that the SQLITE_TEXT constant was also used in SQLite version 2 ** for a completely different meaning. Software that links against both ** SQLite version 2 and SQLite version 3 should use SQLITE3_TEXT, not ** SQLITE_TEXT.

80688. OUTPUT: Declared data type

80689. Free idxStr using sqlite3_free0() if true

80690. ** Provide the ability to override linkage features of the interface.

80691. OUT: SQLite db handle

80692. True if this constraint is usable

80693. ** CAPI3REF: Setting The Subtype Of An SQL Function ** METHOD: sqlite3_context *** The sqlite3_result_subtype(C,T) function causes the subtype of ** the result from the [application-defined SQL function] with ** [sqlite3_context] C to be the value T. Only the lower 8 bits ** of the subtype T are preserved in current versions of SQLite; ** higher order bits are discarded. ** The number of subtype bytes preserved by SQLite might increase ** in future releases of SQLite.

80694. SQLITE3_H

80695. Estimated number of rows returned

80696. **comment:** ** CAPI3REF: Destroy A Prepared Statement Object ** DESTRUCTOR: sqlite3_stmt *** ^The sqlite3_finalize() function is called to delete a [prepared statement]. ** ^If the most recent evaluation of the statement encountered no errors ** or if the statement is never been evaluated, then sqlite3_finalize() returns ** SQLITE_OK. ^If the most recent evaluation of statement S failed, then ** sqlite3_finalize(S) returns the appropriate [error code] or ** [extended error code]. *** ^The sqlite3_finalize(S) routine can be called at any point during ** the life cycle of [prepared statement] S: ** before statement S is ever evaluated, after ** one or more calls to [sqlite3_reset0], or after any call ** to [sqlite3_step0] regardless of whether or not the statement has ** completed execution. *** ^Invoking sqlite3_finalize() on a NULL pointer is a harmless no-op. *** The application must finalize every [prepared statement] in order to avoid ** resource leaks. It is a grievous error for the application to try to use ** a prepared statement after it has been finalized. Any use of a prepared ** statement after it has been finalized can result in undefined and ** undesirable behavior such as segfaults and heap corruption.

label: code-design

80697. Callback function to invoke

80698. **comment:** ** CAPI3REF: Standard File Control Opcodes ** KEYWORDS: {file control opcodes} {file control opcode} *** These integer constants are opcodes for the xFileControl method ** of the [sqlite3_io_methods] object and for the [sqlite3_file_control0] ** interface. *** ** [[SQLITE_FCNTL_LOCKSTATE]] ** The [SQLITE_FCNTL_LOCKSTATE] opcode is used for debugging. This ** opcode causes the xFileControl method to write the current state of ** the lock (one of [SQLITE_LOCK_NONE], [SQLITE_LOCK_SHARED], ** [SQLITE_LOCK_RESERVED], [SQLITE_LOCK_PENDING], or [SQLITE_LOCK_EXCLUSIVE]) ** into an integer that the pArg argument points to. This capability ** is used during testing and is only available when the SQLITE_TEST ** compile-time option is used. *** [[SQLITE_FCNTL_SIZE_HINT]] ** The [SQLITE_FCNTL_SIZE_HINT] opcode is used by SQLite to give the VFS ** layer a hint of how large the database file will grow to be during the ** current transaction. This hint is not guaranteed to be accurate but it ** is often close. The underlying VFS might choose to preallocate database ** file space based on this hint in order to help writes to the database ** file run faster. *** [[SQLITE_FCNTL_CHUNK_SIZE]] ** The [SQLITE_FCNTL_CHUNK_SIZE] opcode is

used to request that the VFS ** extends and truncates the database file in chunks of a size specified ** by the user. The fourth argument to [sqlite3_file_control()] should ** point to an integer (type int) containing the new chunk-size to use ** for the nominated database. Allocating database file space in large ** chunks (say 1MB at a time), may reduce file-system fragmentation and ** improve performance on some systems. *** [[SQLITE_FCNTL_FILE_POINTER]] ** The [SQLITE_FCNTL_FILE_POINTER] opcode is used to obtain a pointer ** to the [sqlite3_file] object associated with a particular database ** connection. See also [SQLITE_FCNTL_JOURNAL_POINTER]. *** [[SQLITE_FCNTL_JOURNAL_POINTER]] ** The [SQLITE_FCNTL_JOURNAL_POINTER] opcode is used to obtain a pointer ** to the [sqlite3_file] object associated with the journal file (either ** the [rollback journal] or the [write-ahead log]) for a particular database ** connection. See also [SQLITE_FCNTL_FILE_POINTER]. *** [[SQLITE_FCNTL_SYNC OMITTED]] ** No longer in use. *** [[SQLITE_FCNTL_SYNC]] ** The [SQLITE_FCNTL_SYNC] opcode is generated internally by SQLite and ** sent to the VFS immediately before the xSync method is invoked on a ** database file descriptor. Or, if the xSync method is not invoked ** because the user has configured SQLite with ** [PRAGMA synchronous | PRAGMA synchronous=OFF] it is invoked in place ** of the xSync method. In most cases, the pointer argument passed with ** this file-control is NULL. However, if the database file is being synced ** as part of a multi-database commit, the argument points to a nul-terminated ** string containing the transactions master-journal file name. VFSes that ** do not need this signal should silently ignore this opcode. Applications ** should not call [sqlite3_file_control()] with this opcode as doing so may ** disrupt the operation of the specialized VFSes that do require it. *** [[SQLITE_FCNTL_COMMIT_PHASETWO]] ** The [SQLITE_FCNTL_COMMIT_PHASETWO] opcode is generated internally by SQLite ** and sent to the VFS after a transaction has been committed immediately ** but before the database is unlocked. VFSes that do not need this signal ** should silently ignore this opcode. Applications should not call ** [sqlite3_file_control()] with this opcode as doing so may disrupt the ** operation of the specialized VFSes that do require it. *** [[SQLITE_FCNTL_WIN32_AV_RETRY]] ** ^The [SQLITE_FCNTL_WIN32_AV_RETRY] opcode is used to configure automatic ** retry counts and intervals for certain disk I/O operations for the ** windows [VFS] in order to provide robustness in the presence of ** anti-virus programs. By default, the windows VFS will retry file read, ** file write, and file delete operations up to 10 times, with a delay ** of 25 milliseconds before the first retry and with the delay increasing ** by an additional 25 milliseconds with each subsequent retry. This ** opcode allows these two values (10 retries and 25 milliseconds of delay) ** to be adjusted. The values are changed for all database connections ** within the same process. The argument is a pointer to an array of two ** integers where the first integer is the new retry count and the second ** integer is the delay. If either integer is negative, then the setting ** is not changed but instead the prior value of that setting is written ** into the array entry, allowing the current retry settings to be ** interrogated. The zDbName parameter is ignored. *** [[SQLITE_FCNTL_PERSIST_WAL]] ** ^The [SQLITE_FCNTL_PERSIST_WAL] opcode is used to set or query the ** persistent [WAL | Write Ahead Log] setting. By default, the auxiliary ** write ahead log and shared memory files used for transaction control ** are automatically deleted when the latest connection to the database ** closes. Setting persistent WAL mode causes those files to persist after ** close. Persisting the files is useful when other processes that do not ** have write permission on the directory containing the database file want ** to read the database file, as the WAL and shared memory files must exist ** in order for the database to be readable. The fourth parameter to ** [sqlite3_file_control()] for this opcode should be a pointer to an integer. ** That integer is 0 to disable persistent WAL mode or 1 to enable persistent ** WAL mode. If the integer is -1, then it is overwritten with the current ** WAL persistence setting. *** [[SQLITE_FCNTL_POWERSAFE_OVERWRITE]] ** ^The [SQLITE_FCNTL_POWERSAFE_OVERWRITE] opcode is used to set or query the ** persistent "powersafe-overwrite" or "PSOW" setting. The PSOW setting ** determines the [SQLITE_IOCAP_POWERSAFE_OVERWRITE] bit of the ** xDeviceCharacteristics methods. The fourth parameter to ** [sqlite3_file_control()] for this opcode should be a pointer to an integer. ** That integer is 0 to disable zero-damage mode or 1 to enable zero-damage ** mode. If the integer is -1, then it is overwritten with the current ** zero-damage mode setting. *** [[SQLITE_FCNTL_OVERWRITE]] ** ^The [SQLITE_FCNTL_OVERWRITE] opcode is invoked by SQLite after opening ** a write transaction to indicate that, unless it is rolled back for some ** reason, the entire database file will be overwritten by the current ** transaction. This is used by VACUUM operations. *** [[SQLITE_FCNTL_VFSNAME]] ** ^The [SQLITE_FCNTL_VFSNAME] opcode can be used to obtain the names of ** all [VFSes] in the VFS stack. The names are of all VFS shims and the ** final bottom-level VFS are written into memory obtained from ** [sqlite3_malloc()] and the result is stored in the char* variable ** that the fourth parameter of [sqlite3_file_control()] points to. ** The caller is responsible for freeing the memory when done. As with ** all file-control actions, there is no guarantee that this will actually ** do anything. Callers should initialize the char* variable to a NULL ** pointer in case this file-control is not implemented. This file-control ** is intended for diagnostic use only. *** [[SQLITE_FCNTL_VFS_POINTER]] ** ^The [SQLITE_FCNTL_VFS_POINTER] opcode finds a pointer to the top-level ** [VFSes] currently in use. ^The argument X in ** sqlite3_file_control(db,SQLITE_FCNTL_VFS_POINTER,X) must be ** of type "[sqlite3_vfs]" **. This opcodes will set *X ** to a pointer to the top-level VFS. ** ^When there are multiple VFS shims in the stack, this opcode finds the ** upper-most shim only. *** [[SQLITE_FCNTL_PRAGMA]] ** ^Whenever a [PRAGMA] statement is parsed, an [SQLITE_FCNTL_PRAGMA] ** file control is sent to the open [sqlite3_file] object corresponding ** to the database file to which the pragma statement refers. ^The argument ** to the [SQLITE_FCNTL_PRAGMA] file control is an array of ** pointers to strings (char**) in which the second element of the array ** is the name of the pragma and the third element is the argument to the ** pragma or NULL if the pragma has no argument. ^The handler for an ** [SQLITE_FCNTL_PRAGMA] file control can optionally make the first element ** of the char** argument point to a string obtained from [sqlite3_mprintf()] ** or the equivalent and that string will become the result of the pragma or ** the error message if the pragma fails. ^If the ** [SQLITE_FCNTL_PRAGMA] file control returns [SQLITE_NOTFOUND], then normal ** [PRAGMA] processing continues. ^If the [SQLITE_FCNTL_PRAGMA] ** file control returns [SQLITE_OK], then the parser assumes that the ** VFS has handled the PRAGMA itself and the parser generates a no-op ** prepared statement if result string is NULL, or that returns a copy ** of the result string if the string is non-NULL. ** ^If the [SQLITE_FCNTL_PRAGMA] file control returns ** any result code other than [SQLITE_OK] or [SQLITE_NOTFOUND], that means ** that the VFS encountered an error while handling the [PRAGMA] and the ** compilation of the PRAGMA fails with an error. ^The [SQLITE_FCNTL_PRAGMA] ** file control occurs at the beginning of pragma statement analysis and so ** it is able to override built-in [PRAGMA] statements. *** [[SQLITE_FCNTL_BUSYHANDLER]] ** ^The [SQLITE_FCNTL_BUSYHANDLER] ** file-control may be invoked by SQLite on the database file handle ** shortly after it is opened in order to provide a custom VFS with access ** to the connections busy-handler callback. The argument is of type (void **) ** - an array of two (void *) values. The first (void *) actually points ** to a function of type (int (*)(void *)). In order to invoke the connections ** busy-handler, this function should be invoked with the second (void *) in ** the array as the only argument. If it returns non-zero, then the operation ** should be retried. If it returns zero, the custom VFS should abandon the ** current operation. *** [[SQLITE_FCNTL_TEMPFILENAME]] ** ^Application can invoke [SQLITE_FCNTL_TEMPFILENAME] file-control ** to have SQLite generate a ** temporary filename using the same algorithm that is followed to generate ** temporary filenames for TEMP tables and other internal uses. The ** argument should be a char** which will be filled with the filename ** written into memory obtained from [sqlite3_malloc()]. The caller should ** invoke [sqlite3_free()] on the result to avoid a memory leak. *** [[SQLITE_FCNTL_MMAP_SIZE]] ** The [SQLITE_FCNTL_MMAP_SIZE] file control is used to query or set the ** maximum number of bytes that will be used for memory-mapped I/O. ** The argument is a pointer to a value of type sqlite3_int64 that ** is an advisory maximum number of bytes in the file to memory map. The ** pointer is overwritten with the old value. The limit is not changed if ** the value originally pointed to is negative, and so the current limit ** can be queried by passing in a pointer to a negative number. This ** file-control is used internally to implement [PRAGMA mmap_size]. *** [[SQLITE_FCNTL_TRACE]] ** ^The [SQLITE_FCNTL_TRACE] file control provides advisory information ** to the VFS about what the higher layers of the SQLite stack are doing. ** This file control is used by some VFS activity tracing [shims]. ** The argument is a zero-terminated string. Higher layers in the ** SQLite stack may generate instances of this file control if ** the [SQLITE_USE_FCNTL_TRACE] compile-time option is enabled. *** [[SQLITE_FCNTL_HAS_MOVED]] ** ^The [SQLITE_FCNTL_HAS_MOVED] file control interprets its argument as a ** pointer to an integer and it writes a boolean into that integer depending ** on whether or not the file has been renamed, moved, or deleted since it ** was first opened. *** [[SQLITE_FCNTL_WIN32_GET_HANDLE]] ** ^The [SQLITE_FCNTL_WIN32_GET_HANDLE] opcode can be used to obtain the ** underlying native file handle associated with a file handle. This file ** control interprets its argument as a pointer to a native file handle and ** writes the resulting value there. *** [[SQLITE_FCNTL_WIN32_SET_HANDLE]] ** ^The [SQLITE_FCNTL_WIN32_SET_HANDLE] opcode is used for debugging. This ** opcode causes the xFileControl method to swap the file handle with the one ** pointed to by the pArg argument. This capability is used during testing ** and only needs to be supported when SQLITE_TEST is defined. *** [[SQLITE_FCNTL_WAL_BLOCK]] ** ^The [SQLITE_FCNTL_WAL_BLOCK] is a signal to the VFS layer that it might ** be advantageous to block on the next WAL lock if the lock is not immediately ** available. The WAL subsystem issues this signal during rare ** circumstances in order to fix a problem with priority inversion. ** Applications should not use this file-control. *** [[SQLITE_FCNTL_ZIPVFS]] ** ^The [SQLITE_FCNTL_ZIPVFS] opcode is implemented by zipvfs only. All other ** VFS should return SQLITE_NOTFOUND for this opcode. *** [[SQLITE_FCNTL_RBU]] ** ^The [SQLITE_FCNTL_RBU] opcode is implemented by the special VFS used by ** the RBU extension only. All other VFS should return SQLITE_NOTFOUND for ** this opcode. **

80724. ** CAPI3REF: Overload A Function For A Virtual Table ** METHOD: sqlite3 *** ^Virtual tables can provide alternative implementations of functions ** using the [xFindFunction] method of the [virtual table module]. ** But global versions of those functions ** must exist in order to be overloaded.)** ** ^This API makes sure a global version of a function with a particular ** name and number of parameters exists. If no such function exists ** before this API is called, a new function is created.)** ^The implementation ** of the new function always causes an exception to be thrown. So ** the new function is not good for anything by itself. Its only ** purpose is to be a placeholder function that can be overloaded ** by a [virtual table].

80725. OUTPUT: True if NOT NULL constraint exists

80726. Unable to open the database file

80727. ** Specify the activation key for a SEE database. Unless ** activated, none of the SEE routines will work.

80728. ** Allowed values for sqlite3_rtree_query.eWithin and .eParentWithin.

80729. **comment:** ** CAPI3REF: Streaming Versions of API functions. *** The six streaming API xxx_strm() functions serve similar purposes to the ** corresponding non-streaming API functions: *** <table border=1 style="margin-left:8ex;margin-right:8ex"> ** <tr><th>Streaming function</th>Non-streaming equivalent</th> ** <tr><td>sqlite3changeset_apply<td>[sqlite3changeset_apply] ** <tr><td>sqlite3changeset_concat<td>[sqlite3changeset_concat] ** <tr><td>sqlite3changeset_invert<td>[sqlite3changeset_invert] ** <tr><td>sqlite3changeset_start<td>[sqlite3changeset_start] ** <tr><td>sqlite3session_changeset<td>[sqlite3session_changeset] ** <tr><td>sqlite3session_patchset<td>[sqlite3session_patchset] ** </table> *** Non-streaming functions that accept changesets (or patchsets) as input ** require that the entire changeset be stored in a single buffer in memory. ** Similarly, those that return a changeset or patchset do so by returning ** a pointer to a single large buffer allocated using sqlite3_malloc(). ** Normally this is convenient. However, if an application running in a ** low-memory environment is required to handle very large changesets, the ** large contiguous memory allocations required can become onerous. ** In order to avoid this problem, instead of a single large buffer, input ** is passed to a streaming API functions by way of a callback function that ** the sessions module invokes to incrementally request input data as it is ** required. In all cases, a pair of API function parameters such as *** <pre> ** &nbs; int nChangeset, ** &nbs; void *pChangeset, ** </pre> ** Is replaced by: *** <pre> ** &nbs; int (*xInput)(void *pIn, void *pData, int *pnData), ** &nbs; void *pIn, ** </pre> ** Each time the xInput callback is invoked by the sessions module, the first ** argument passed is a copy of the supplied pIn context pointer. The second ** argument, pData, points to a buffer (*pnData) bytes in size. Assuming no ** error occurs the xInput method should copy up to (*pnData) bytes of data ** into the buffer and set (*pnData) to the actual number of bytes copied ** before returning SQLITE_OK. If the input is completely exhausted, (*pnData) ** should be set to zero to indicate this. Or, if an error occurs, an SQLite ** error code should be returned. In all cases, if an xInput callback returns ** an error, all processing is abandoned and the streaming API function ** returns a copy of the error code to the caller. *** In the case of sqlite3changeset_start_strm(), the xInput callback may be ** invoked by the sessions module at any point during the lifetime of the ** iterator. If such an xInput callback returns an error, the iterator enters ** an error state, whereby all subsequent calls to iterator functions ** immediately fail with the same error code as returned by xInput. ** Similarly, streaming API functions that return changesets (or patchsets) ** return them in chunks by way of a callback function instead of via a ** pointer to a single large buffer. In this case, a pair of parameters such ** as: *** <pre> ** &nbs; int *pnChangeset, ** &nbs; void **ppChangeset, ** </pre> ** Is replaced by: *** <pre> ** &nbs; int (*xOutput)(void *pOut, const void *pData, int nData), ** &nbs; void *pOut ** </pre> ** The xOutput callback is invoked zero or more times to return data to ** the application. The first parameter passed to each call is a copy of the ** pOut pointer supplied by the application. The second parameter, pData, ** points to a buffer nData bytes in size containing the chunk of output ** data being returned. If the xOutput callback successfully processes the ** supplied data, it should return SQLITE_OK to indicate success. Otherwise, ** it should return some other SQLite error code. In this case processing ** is immediately abandoned and the streaming API function returns a copy ** of the xOutput error code to the application. ** The sessions module never invokes an xOutput callback with the third ** parameter set to a value less than or equal to zero. Other than this, ** no guarantees are made as to the size of the chunks of data returned.

80742. ** CAPI3REF: Prepared Statement Object ** KEYWORDS: {prepared statement} {prepared statements} ** ** An instance of this object represents a single SQL statement that ** has been compiled into binary form and is ready to be evaluated. ** ** Think of each SQL statement as a separate computer program. The ** original SQL text is source code. A prepared statement object ** is the compiled object code. All SQL must be converted into a ** prepared statement before it can be run. ** ** The life-cycle of a prepared statement object usually goes like this: *** ** Create the prepared statement object using [sqlite3_prepare_v2()]. ** Bind values to [parameters] using the sqlite3_bind_*() ** interfaces. ** Run the SQL by calling [sqlite3_step()] one or more times. ** Reset the prepared statement using [sqlite3_reset()] then go back ** to step 2. Do this zero or more times. ** Destroy the object using [sqlite3_finalize()]. **

80743. Initialize the memory allocator

80744. **comment:** ** CAPI3REF: Convenience Routines For Running Queries ** METHOD: sqlite3 *** This is a legacy interface that is preserved for backwards compatibility. ** Use of this interface is not recommended. ** ** Definition: A result table is memory data structure created by the ** [sqlite3_get_table()] interface. A result table records the ** complete query results from one or more queries. ** ** The table conceptually has a number of rows and columns. But ** these numbers are not part of the result table itself. These ** numbers are obtained separately. Let N be the number of rows ** and M be the

number of columns. *** A result table is an array of pointers to zero-terminated UTF-8 strings. ** There are (N+1)*M elements in the array. The first M pointers point ** to zero-terminated strings that contain the names of the columns. ** The remaining entries all point to query results. NULL values result ** in NULL pointers. All other values are in their UTF-8 zero-terminated ** string representation as returned by [sqlite3_column_text()]. *** A result table might consist of one or more memory allocations. ** It is not safe to pass a result table directly to [sqlite3_free()]. ** A result table should be deallocated using [sqlite3_free_table()]. *** ^As an example of the result table format, suppose a query result ** is as follows: *** <blockquote><pre> ** Name | Age ** -----
----- ** Alice | 43 ** Bob | 28 ** Cindy | 21 ** </pre></blockquote> *** There are two column (M==2) and three rows (N==3). Thus the ** result table has 8 entries. Suppose the result table is stored ** in an array names azResult. Then azResult holds this content: *** <blockquote><pre> ** azResult[0] = "Name"; ** azResult[1] = "Age"; ** azResult[2] = "Alice"; ** azResult[3] = "43"; ** azResult[4] = "Bob"; ** azResult[5] = "28"; ** azResult[6] = "Cindy"; ** azResult[7] = "21"; ** </pre></blockquote> *** ^The sqlite3_get_table() function evaluates one or more ** semicolon-separated SQL statements in the zero-terminated UTF-8 ** string of its 2nd parameter and returns a result table to the ** pointer given in its 3rd parameter. *** After the application has finished with the result from sqlite3_get_table(), ** it must pass the result table pointer to sqlite3_free_table() in order to ** release the memory that was malloced. Because of the way the ** [sqlite3_malloc()] happens within sqlite3_get_table(), the calling ** function must not try to call [sqlite3_free()] directly. Only ** [sqlite3_free_table()] is able to release the memory properly and safely. *** ^The sqlite3_get_table() interface is implemented as a wrapper around ** [sqlite3_exec()]. The sqlite3_get_table() routine does not have access ** to any internal data structures of SQLite. It uses only the public ** interface defined here. As a consequence, errors that occur in the ** wrapper layer outside of the internal [sqlite3_exec()] call are not ** reflected in subsequent calls to [sqlite3_errcode()] or ** [sqlite3_errmsg()].

label: code-design

80745. ** CAPI3REF: Source Of Data In A Query Result ** METHOD: sqlite3_stmt ** ** ^These routines provide a means to determine the database, table, and ** table column that is the origin of a particular result column in ** [SELECT] statement. ** ^The name of the database or table or column can be returned as ** either a UTF-8 or UTF-16 string. ^The _database_ routines return ** the database name, the _table_ routines return the table name, and ** the origin_ routines return the column name. ** ^The returned string is valid until the [prepared statement] is destroyed ** using [sqlite3_finalize()] or until the statement is automatically ** reprepared by the first call to [sqlite3_step()] for a particular run ** or until the same information is requested ** again in a different encoding. ** ** ^The names returned are the original un-aliased names of the ** database, table, and column. *** ^The first argument to these interfaces is a [prepared statement]. ** ^These functions return information about the Nth result column returned by ** the statement, where N is the second function argument. ** ^The left-most column is column 0 for these routines. *** ^If the Nth column returned by the statement is an expression or ** subquery and is not a column value, then all of these functions return ** NULL. ^These routine might also return NULL if a memory allocation error ** occurs. ^Otherwise, they return the name of the attached database, table, ** or column that query result column was extracted from. *** ^As with all other SQLite APIs, those whose names end with "16" return ** UTF-16 encoded strings and the other functions return UTF-8. *** ^These APIs are only available if the library was compiled with the ** [SQLITE_ENABLE_COLUMN_METADATA] C-preprocessor symbol. *** If two or more threads call one or more of these routines against the same ** prepared statement and column at the same time then the results are ** undefined. *** If two or more threads call one or more ** [sqlite3_column_database_name | column metadata interfaces] ** for the same [prepared statement] and result column ** at the same time then the results are undefined.

80746. ** The methods above are in versions 1 and 2 of the sqlite_vfs object. ** Those below are for version 3 and greater.

80747. ** CAPI3REF: Configure an auto-checkpoint ** METHOD: sqlite3 ** ** ^The [sqlite3_wal_autocheckpoint(D,N)] is a wrapper around ** [sqlite3_wal_hook()] that causes any database on [database connection] D ** to automatically [checkpoint] ** after committing a transaction if there are N or ** more frames in the [write-ahead log] file. ^Passing zero or ** a negative value as the nFrame parameter disables automatic ** checkpoints entirely. *** ^The callback registered by this function replaces any existing callback ** registered using [sqlite3_wal_hook()]. ^Likewise, registering a callback ** using [sqlite3_wal_hook()] disables the automatic checkpoint mechanism ** configured by this function. *** ^The [wal_autocheckpoint pragma] can be used to invoke this interface ** from SQL. ** ** ^Checkpoints initiated by this mechanism are ** [sqlite3_wal_checkpoint_v2|PASSIVE]. *** ^Every new [database connection] defaults to having the auto-checkpoint ** enabled with a threshold of 1000 or [SQLITE_DEFAULT_WAL_AUTOCHECKPOINT] ** pages. The use of this interface ** is only necessary if the default setting is found to be suboptimal ** for a particular application.

80761. Name of db (e.g. "main")

80762. ** CAPI3REF: Set A Busy Timeout ** METHOD: sqlite3 *** ^This routine sets a [sqlite3_busy_handler | busy handler] that sleeps ** for a specified amount of time when a table is locked. ^The handler ** will sleep multiple times until at least "ms" milliseconds of sleeping ** have accumulated. ^After at least "ms" milliseconds of sleeping, ** the handler returns 0 which causes [sqlite3_step()] to return ** [SQLITE_BUSY]. *** ^Calling this routine with an argument less than or equal to zero ** turns off all busy handlers. *** ^There can only be a single busy handler for a particular ** [database connection] at any given moment. If another busy handler ** was defined (using [sqlite3_busy_handler()]) prior to calling ** this routine, that other busy handler is cleared.)^ *** See also: [PRAGMA busy_timeout]

80763. **comment:** ** CAPI3REF: Compiling An SQL Statement ** KEYWORDS: {SQL statement compiler} ** METHOD: sqlite3 *** CONSTRUCTOR: sqlite3_stmt *** To execute an SQL statement, it must first be compiled into a byte-code ** program using one of these routines. Or, in other words, these routines ** are constructors for the [prepared statement] object. *** ^The preferred routine to use is [sqlite3_prepare_v2()]. The ** [sqlite3_prepare()] interface is legacy and should be avoided. ** [sqlite3_prepare_v3()] has an extra "prepFlags" option that is used ** for special purposes. *** ^The use of the UTF-8 interfaces is preferred, as SQLite currently ** does all parsing using UTF-8. The UTF-16 interfaces are provided ** as a convenience. The UTF-16 interfaces work by converting the ** input text into UTF-8, then invoking the corresponding UTF-8 interface. *** ^The first argument, "db", is a [database connection] obtained from a ** prior successful call to [sqlite3_open()], [sqlite3_open_v2()] or ** [sqlite3_open16()]. The database connection must not have been closed. *** ^The second argument, "zSql", is the statement to be compiled, encoded ** as either UTF-8 or UTF-16. The sqlite3_prepare(), sqlite3_prepare_v2(), ** and sqlite3_prepare_v3() ** interfaces use UTF-8, and sqlite3_prepare16(), sqlite3_prepare16_v2(), ** and sqlite3_prepare16_v3() use UTF-16. *** ^If the nByte argument is negative, then zSql is read up to the ** first zero terminator. ^If nByte is positive, then it is the ** number of bytes read from zSql. ^If nByte is zero, then no prepared ** statement is generated. ** If the caller knows that the supplied string is nul-terminated, then ** there is a small performance advantage to passing an nByte parameter that ** is the number of bytes in the input string <i>including</i> ** the nul-terminator. *** ^If pzTail is not NULL then *pzTail is made to point to the first byte ** past the end of the first SQL statement in zSql. These routines only ** compile the first statement in zSql, so *pzTail is left pointing to ** what remains uncompiled. *** ^ppStmt is left pointing to a compiled [prepared statement] that can be ** executed using [sqlite3_step()]. ^If there is an error, *ppStmt is set ** to NULL. ^If the input text contains no SQL (if the input is an empty ** string or a comment) then *ppStmt is set to NULL. ** The calling procedure is responsible for deleting the compiled ** SQL statement using [sqlite3_finalize()] after it has finished with it. ** ppStmt may not be NULL. *** ^On success, the sqlite3_prepare() family of routines return [SQLITE_OK]; ** otherwise an [error code] is returned. *** ^The sqlite3_prepare_v2(), sqlite3_prepare_v3(), sqlite3_prepare16_v2(), ** and sqlite3_prepare16_v3() interfaces are recommended for all new programs. ** The older interfaces (sqlite3_prepare() and sqlite3_prepare16()) ** are retained for backwards compatibility, but their use is discouraged. *** ^In the "vX" interfaces, the prepared statement ** that is returned (the [sqlite3_stmt] object) contains a copy of the ** original SQL text. This causes the [sqlite3_step()] interface to ** behave differently in three ways: *** ** ** ** ^If the database schema changes, instead of returning [SQLITE_SCHEMA] as it ** always used to do, [sqlite3_step()] will automatically recompile the SQL ** statement and try to run it again. As many as [SQLITE_MAX_SCHEMA_RETRY] ** retries will occur before sqlite3_step() gives up and returns an error. ** ** ** ^When an error occurs, [sqlite3_step()] will return one of the detailed ** [error codes] or [extended error codes]. ^The legacy behavior was that ** [sqlite3_step()] would only return a generic [SQLITE_ERROR] result code ** and the application would have to make a second call to [sqlite3_reset()] ** in order to find the underlying cause of the problem. With the "v2" prepare ** interfaces, the underlying reason for the error is returned immediately. ** ** ** ^If the specific value bound to [parameter] host parameter] in the ** WHERE clause might influence the choice of query plan for a statement, ** then the statement will be automatically recompiled, as if there had been ** a schema change, on the first [sqlite3_step()] call following any change ** to the [sqlite3_bind_text | bindings] of that [parameter]. ** ^The specific value of WHERE-clause [parameter] might influence the ** choice of query plan if the parameter is the left-hand side of a [LIKE] ** or [GLOB] operator or if the parameter is compared to an indexed column ** and the [SQLITE_ENABLE_STAT3] compile-time option is enabled. ** ** <p>^A sqlite3_prepare_v3() differs from sqlite3_prepare_v2() only in having ** the extra prepFlags parameter, which is a bit array consisting of zero or ** more of the [SQLITE_PERSISTENT|SQLITE_PREPARE_*] flags. ^The ** sqlite3_prepare_v2() interface works exactly the same as ** sqlite3_prepare_v3() with a zero prepFlags parameter. **

80765. ** CAPI3REF: Attach A Table To A Session Object ** ** If argument zTab is not NULL, then it is the name of a table to attach ** to the session object passed as the first argument. All subsequent changes ** made to the table while the session object is enabled will be recorded. See ** documentation for [sqlite3session_changeset()] for further details. *** ^Or, if argument zTab is NULL, then changes are recorded for all tables ** in the database. If additional tables are added to the database (by ** executing "CREATE TABLE" statements) after this call is made, changes for ** the new tables are also recorded. *** ^Changes can only be recorded for tables that have a PRIMARY KEY explicitly ** defined as part of their CREATE TABLE statement. It does not matter if the ** PRIMARY KEY is an "INTEGER PRIMARY KEY" (rowid alias) or not. The PRIMARY ** KEY may consist of a single column, or may be a composite key. ** ** It is not an error if the named table does not exist in the database. Nor ** is it an error if the named table does not have a PRIMARY KEY. However, ** no changes will be recorded in either of these scenarios. *** ^Changes are not recorded for individual rows that have NULL values stored ** in one or more of their PRIMARY KEY columns. *** ^SQLITE_OK is returned if the call completes without error. Or, if an error ** occurs, an SQLite error code (e.g. SQLITE_NOMEM) is returned.

80766. **comment:** ** CAPI3REF: Binding Values To Prepared Statements ** KEYWORDS: {host parameter} {host parameters} {host parameter name} **

KEYWORDS: {SQL parameter} {SQL parameters} {parameter binding} ** METHOD: sqlite3_stmt *** ^In the SQL statement text input to [sqlite3_prepare_v2()] and its variants, ** literals may be replaced by a [parameter] that matches one of following ** templates: *** ** ? ** ? NNN ** :VVV ** @VVV ** \$VVV ** ** ^In the templates above, NNN represents an integer literal, ** and VVV represents an alphanumeric identifier.)^ ^The values of these ** parameters (also called "host parameter names" or "SQL parameters") ** can be set using the sqlite3_bind_*() routines defined here. *** ^The first argument to the sqlite3_bind_*() routines is always ** a pointer to the [sqlite3_stmt] object returned from **

[sqlite3_prepare_v2()] or its variants. ** ** ^The second argument is the index of the SQL parameter to be set. ** ^The leftmost SQL parameter has an index of 1. ^When the same named ** SQL parameter is used more than once, second and subsequent ** occurrences have the same index as the first occurrence. ** ^The index for named parameters can be looked up using the ** [sqlite3_bind_parameter_index()] API if desired. ^The index ** for "?NNN" parameters is the value of NNN. ** ^The NNN value must be between 1 and the [sqlite3_limit()] ** parameter [SQLITE_LIMIT_VARIABLE_NUMBER] (default value: 999). ** ** ^The third argument is the value to bind to the parameter. ** ^If the third parameter to sqlite3_bind_text() or sqlite3_bind_text16() ** or sqlite3_bind_blob() is a NULL pointer then the fourth parameter ** is ignored and the end result is the same as sqlite3_bind_null(). ** ** ^In those routines that have a fourth argument, its value is the ** number of bytes in the parameter. To be clear: the value is the ** number of <u>bytes</u> in the value, not the number of characters.)^ ** ^If the fourth parameter to sqlite3_bind_text() or sqlite3_bind_text16() ** is negative, then the length of the string is ** the number of bytes up to the first zero terminator. ** If the fourth parameter to sqlite3_bind_blob() is negative, then ** the behavior is undefined. ** If a non-negative fourth parameter is provided to sqlite3_bind_text() ** or sqlite3_bind_text16() or sqlite3_bind_text64() then ** that parameter must be the byte offset ** where the NUL terminator would occur assuming the string were NUL ** terminated. If any NUL characters occur at byte offsets less than ** the value of the fourth parameter then the resulting string value will ** contain embedded NULs. The result of expressions involving strings ** with embedded NULs is undefined. ** ** ^The fifth argument to the BLOB and string binding interfaces ** is a destructor used to dispose of the BLOB or ** string after SQLite has finished with it. ^The destructor is called ** to dispose of the BLOB or string even if the call to bind API fails. ** ^If the fifth argument is ** the special value [SQLITE_STATIC], then SQLite assumes that the ** information is in static, unmanaged space and does not need to be freed. ** ^If the fifth argument has the value [SQLITE_TRANSIENT], then ** SQLite makes its own private copy of the data immediately, before ** the sqlite3_bind_*() routine returns. ** ** ^The sixth argument to sqlite3_bind_text64() must be one of ** [SQLITE_UTF8], [SQLITE_UTF16], [SQLITE_UTF16BE], or [SQLITE_UTF16LE] ** to specify the encoding of the text in the third parameter. If ** the sixth argument to sqlite3_bind_text64() is not one of the ** allowed values shown above, or if the text encoding is different ** from the encoding specified by the sixth parameter, then the behavior ** is undefined. ** ** ^The sqlite3_bind_zeroblob() routine binds a BLOB of length N that ** is filled with zeroes. ^A zeroblob uses a fixed amount of memory ** (just an integer to hold its size) while it is being processed. ** Zeroblobs are intended to serve as placeholders for BLOBs whose ** content is later written using ** [sqlite3_blob_open | incremental BLOB I/O] routines. ** ^A negative value for the zeroblob results in a zero-length BLOB. ** ** ^The sqlite3_bind_pointer(S,I,P,T,D) routine causes the I-th parameter in ** [prepared statement] S to have an SQL value of NULL, but to also be ** associated with the pointer P of type T. ^D is either a NULL pointer or ** a pointer to a destructor function for P. ^SQLite will invoke the ** destructor D with a single argument of P when it is finished using ** P. The T parameter should be a static string, preferably a string ** literal. The sqlite3_bind_pointer() routine is part of the ** [pointer passing interface] added for SQLite 3.20.0. ** ** ^If any of the sqlite3_bind_*() routines are called with a NULL pointer ** for the [prepared statement] or with a prepared statement for which ** [sqlite3_step()] has been called more recently than [sqlite3_reset()], ** then the call will return [SQLITE_MISUSE]. If any sqlite3_bind_*() ** routine is passed a [prepared statement] that has been finalized, the ** result is undefined and probably harmful. ** ** ^Bindings are not cleared by the [sqlite3_reset()] routine. ** ^Unbound parameters are interpreted as NULL. ** ** ^The sqlite3_bind_* routines return [SQLITE_OK] on success or an ** [error code] if anything goes wrong. ** ^[SQLITE_TOOBIG] might be returned if the size of a string or BLOB ** exceeds limits imposed by [sqlite3_limit()][SQLITE_LIMIT_LENGTH] or ** [SQLITE_MAX_LENGTH]. ** ^[SQLITE_RANGE] is returned if the parameter ** index is out of range. ^[SQLITE_NOMEM] is returned if malloc() fails. ** ** See also: [sqlite3_bind_parameter_count()], ** [sqlite3_bind_parameter_name()], and [sqlite3_bind_parameter_index()].

80804. ** CAPI3REF: Virtual Table Cursor Object ** KEYWORDS: sqlite3_vtab_cursor {virtual table cursor} *** Every [virtual table module] implementation uses a subclass of the ** following structure to describe cursors that point into the ** [virtual table] and are used ** to loop through the virtual table. Cursors are created using the ** [sqlite3_module.xOpen | xOpen] method of the module and are destroyed ** by the [sqlite3_module.xClose | xClose] method. Cursors are used ** by the [xFilter], [xNext], [xEof], [xColumn], and [xRowid] methods ** of the module. Each module implementation will define ** the content of a cursor structure to suit its own needs. *** This superclass exists in order to define fields of the cursor that ** are common to all implementations.

80805. Column name

80806. Currently always set to 2

80807. First arg for xInput

80808. **comment:** ** CAPI3REF: OS Interface Object ** ** An instance of the sqlite3_vfs object defines the interface between ** the SQLite core and the underlying operating system. The "vfs" ** in the name of the object stands for "virtual file system". See ** the [VFS | VFS documentation] for further information. *** The value of the iVersion field is initially 1 but may be larger in ** future versions of SQLite. Additional fields may be appended to this ** object when the iVersion value is increased. Note that the structure ** of the sqlite3_vfs object changes in the transaction between ** SQLite version 3.5.9 and 3.6.0 and yet the iVersion field was not ** modified. *** The szOsFile field is the size of the subclassed [sqlite3_file] ** structure used by this VFS. mxPathname is the maximum length of ** a pathname in this VFS. *** Registered sqlite3_vfs objects are kept on a linked list formed by ** the pNext pointer. The [sqlite3_vfs_register()] ** and [sqlite3_vfs_unregister()] interfaces manage this list ** in a thread-safe way. The [sqlite3_vfs_find()] interface ** searches the list. Neither the application code nor the VFS ** implementation should use the pNext pointer. *** ^The pNext field is the only field in the sqlite3_vfs ** structure that SQLite will ever modify. SQLite will only access ** or modify this field while holding a particular static mutex. ** The application should never modify anything within the sqlite3_vfs ** object once the object has been registered. *** ^The zName field holds the name of the VFS module. The name must ** be unique across all VFS modules. *** [[sqlite3_vfs.xOpen]] ** ^SQLite guarantees that the zFilename parameter to xOpen ** is either a NULL pointer or string obtained ** from xFullPathname() with an optional suffix added. ** ^If a suffix is added to the zFilename parameter, it will ** consist of a single "-" character followed by no more than ** 11 alphanumeric and/or "-" characters. ** ^SQLite further guarantees that ** the string will be valid and unchanged until xClose() is ** called. Because of the previous sentence, ** the [sqlite3_file] can safely store a pointer to the ** filename if it needs to remember the filename for some reason. ** If the zFilename parameter to xOpen is a NULL pointer then xOpen ** must invent its own temporary name for the file. ^Whenever the ** xFilename parameter is NULL it will also be the case that the ** flags parameter will include [SQLITE_OPEN_DELETEONCLOSE]. *** ^The flags argument to xOpen() includes all bits set in ** the flags argument to [sqlite3_open_v2()]. Or if [sqlite3_open()] ** or [sqlite3_open16()] is used, then flags includes at least ** [SQLITE_OPEN_READWRITE] | [SQLITE_OPEN_CREATE]. ** If xOpen() opens a file read-only then it sets *pOutFlags to ** include [SQLITE_OPEN_READONLY]. Other bits in *pOutFlags may be set. *** ^SQLite will also add one of the following flags to the xOpen() ** call, depending on the object being opened: *** ** [SQLITE_OPEN_MAIN_DB] ** [SQLITE_OPEN_MAIN_JOURNAL] ** [SQLITE_OPEN_TEMP_DB] ** [SQLITE_OPEN_TEMP_JOURNAL] ** [SQLITE_OPEN_TRANSIENT_DB] ** [SQLITE_OPEN_SUBJOURNAL] ** [SQLITE_OPEN_MASTER_JOURNAL] ** [SQLITE_OPEN_WAL] ** *** ^The file I/O implementation can use the object type flags to ** change the way it deals with files. For example, an application ** that does not care about crash recovery or rollback might make ** the open of a journal file a no-op. Writes to this journal would ** also be no-ops, and any attempt to read the journal would return ** SQLITE_IOERR. Or the implementation might recognize that a database ** file will be doing page-aligned sector reads and writes in a random ** order and set up its I/O subsystem accordingly. *** ^SQLite might also add one of the following flags to the xOpen method: *** ** [SQLITE_OPEN_DELETEONCLOSE] ** [SQLITE_OPEN_EXCLUSIVE] ** *** ^The [SQLITE_OPEN_DELETEONCLOSE] flag means the file should be ** deleted when it is closed. ^The [SQLITE_OPEN_DELETEONCLOSE] ** will be set for TEMP databases and their journals, transient ** databases, and subjournals. *** ^The [SQLITE_OPEN_EXCLUSIVE] flag is always used in conjunction ** with the [SQLITE_OPEN_CREATE] flag, which are both directly ** analogous to the O_EXCL and O_CREAT flags of the POSIX open() ** API. The SQLITE_OPEN_EXCLUSIVE flag, when paired with the ** SQLITE_OPEN_CREATE, is used to indicate that file should always ** be created, and that it is an error if it already exists. ** It is <i>not</i> used to indicate the file should be opened ** for exclusive access. *** ^At least szOsFile bytes of memory are allocated by SQLite ** to hold the [sqlite3_file] structure passed as the third ** argument to xOpen. The xOpen method does not have to ** allocate the structure; it should just fill it in. Note that ** the xOpen method must set the sqlite3_file.pMethods to either ** a valid [sqlite3_io_methods] object or to NULL. xOpen must do ** this even if the open fails. SQLite expects that the sqlite3_file.pMethods ** element will be valid after xOpen returns regardless of the success ** or failure

of the xOpen call. *** [[sqlite3_vfs.xAccess]] *** ^The flags argument to xAccess() may be [SQLITE_ACCESS_EXISTS] ** to test for the existence of a file, or [SQLITE_ACCESS_READWRITE] to ** test whether a file is readable and writable, or [SQLITE_ACCESS_READ] ** to test whether a file is at least readable. The file can be a ** directory. *** ^SQLite will always allocate at least mxPathname+1 bytes for the ** output buffer xFullPathname. The exact size of the output buffer ** is also passed as a parameter to both methods. If the output buffer ** is not large enough, [SQLITE_CANTOPEN] should be returned. Since this is ** handled as a fatal error by SQLite, vfs implementations should endeavor ** to prevent this by setting mxPathname to a sufficiently large value. *** ^The xRandomness(), xSleep(), xCurrentTime(), and xCurrentTimeInt64() ** interfaces are not strictly a part of the filesystem, but they are ** included in the VFS structure for completeness. ** The xRandomness() function attempts to return nBytes bytes ** of good-quality randomness into zOut. The return value is ** the actual number of bytes of randomness obtained. ** The xSleep() method causes the calling thread to sleep for at ** least the number of microseconds given. ^The xCurrentTime() ** method returns a Julian Day Number for the current date and time as ** a floating point value. *** ^The xCurrentTimeInt64() method returns, as an integer, the Julian ** Day Number multiplied by 86400000 (the number of milliseconds in ** a 24-hour day). *** ^SQLite will use the xCurrentTimeInt64() method to get the current ** date and time if that method is available (if iVersion is 2 or ** greater and the function pointer is not NULL) and will fall back ** to xCurrentTime() if xCurrentTimeInt64() is unavailable. *** ^The xSetSystemCall(), xGetSystemCall(), and xNestSystemCall() interfaces ** are not used by the SQLite core. These optional interfaces are provided ** by some VFSes to facilitate testing of the VFS code. By overriding ** system calls with functions under its control, a test program can ** simulate faults and error conditions that would otherwise be difficult ** or impossible to induce. The set of system calls that can be overridden ** varies from one VFS to another, and from one version of the same VFS to the ** next. Applications that use these interfaces must be prepared for any ** or all of these interfaces to be NULL or for their behavior to change ** from one release to the next. Applications must not attempt to access ** any of these methods if the iVersion of the VFS is less than 3.

80834. First argument passed to xConflict

80835. Generic error

80836. ** CAPI3REF: Create A New Changegroup Object ** An sqlite3_changegroup object is used to combine two or more changesets ** (or patchsets) into a single changeset (or patchset). A single changegroup ** object may combine changesets or patchsets, but not both. The output is ** always in the same format as the input. ** ^*If successful, this function returns SQLITE_OK and populates (*pp) with ** a pointer to a new sqlite3_changegroup object before returning. The caller ** should eventually free the returned object using a call to ** sqlite3changegroup_delete(). If an error occurs, an SQLite error code ** (i.e. SQLITE_NOMEM) is returned and *pp is set to NULL.* *** ^*The usual usage pattern for an sqlite3_changegroup object is as follows:* *** ** It is created using a call to sqlite3changegroup_new(). ** Zero or more changesets (or patchsets) are added to the object ** by calling sqlite3changegroup_add(). ** The result of combining all input changesets together is obtained ** by the application via a call to sqlite3changegroup_output(). ** The object is deleted using a call to sqlite3changegroup_delete(). ** ** Any number of calls to add() and output() may be made between the calls to ** new() and delete(), and in any order. ** ^*As well as the regular sqlite3changegroup_add() and ** sqlite3changegroup_output() functions, also available are the streaming ** versions sqlite3changegroup_add_strm() and sqlite3changegroup_output_strm().*

80837. ** CAPI3REF: Flush caches to disk mid-transaction ** ^*If a write-transaction is open on [database connection] D when the ** [sqlite3_db_cacheflush(D)] interface invoked, any dirty ** pages in the pager-cache that are not currently in use are written out ** to disk. A dirty page may be in use if a database cursor created by an ** active SQL statement is reading from it, or if it is page 1 of a database ** file (page 1 is always "in use"). ^The [sqlite3_db_cacheflush(D)] ** interface flushes caches for all schemas - "main", "temp", and ** any [attached] databases. ** ^*If this function needs to obtain extra database locks before dirty pages ** can be flushed to disk, it does so. ^If those locks cannot be obtained ** immediately and there is a busy-handler callback configured, it is invoked ** in the usual manner. ^If the required lock still cannot be obtained, then ** the database is skipped and an attempt made to flush any dirty pages ** belonging to the next (if any) database. ^If any databases are skipped ** because locks cannot be obtained, but no other error occurs, this ** function returns SQLITE_BUSY. ** ^*If any other error occurs while flushing dirty pages to disk (for ** example an IO error or out-of-memory condition), then processing is ** abandoned and an SQLite [error code] is returned to the caller immediately. ** ^*Otherwise, if no error occurs, [sqlite3_db_cacheflush()] returns SQLITE_OK.* ** ^*This function does not set the database handle error code or message ** returned by the [sqlite3_errcode()] and [sqlite3_errmsg()] functions.****

80838. ** CAPI3REF: Authorizer Action Codes ** The [sqlite3_set_authorizer()] interface registers a callback function ** that is invoked to authorize certain SQL statement actions. The ** second parameter to the callback is an integer code that specifies ** what action is being authorized. These are the integer action codes that ** the authorizer callback may be passed. ** ^*These action code values signify what kind of operation is to be ** authorized. The 3rd and 4th parameters to the authorization ** callback function will be parameters or NULL depending on which of these ** codes is used as the second parameter. ^*(The 5th parameter to the ** authorizer callback is the name of the database ("main", "temp", ** etc.) if applicable.)* ^*The 6th parameter to the authorizer callback ** is the name of the inner-most trigger or view that is responsible for ** the access attempt or NULL if this access attempt is directly from ** top-level SQL code.**

80839. Entry point. Derived from zFile if 0

80840. Mask of SQLITE_INDEX_SCAN_* flags

80841. ** CAPI3REF: SQL Function Context Object ** The context in which an SQL function executes is stored in an ** sqlite3_context object. ^A pointer to an sqlite3_context object ** is always first parameter to [application-defined SQL functions]. ** ^*The application-defined SQL function implementation will pass this ** pointer through into calls to [sqlite3_result_int] | [sqlite3_result()], ** [sqlite3_aggregate_context()], [sqlite3_user_data()], ** [sqlite3_context_db_handle()], [sqlite3_get_auxdata()], ** and/or [sqlite3_set_auxdata()].*

80842. Copy of 2nd argument to xTokenize()

80843. Table Name NULL

80844. ** A pointer to a structure of the following type is passed as the first ** argument to callbacks registered using rtree_geometry_callback().

80845. **comment:** ** CAPI3REF: Obtain Conflicting Row Values From A Changeset Iterator ** This function should only be used with iterator objects passed to a ** conflict-handler callback by [sqlite3changeset_apply()] with either ** [SQLITE_CHANGESET_DATA] or [SQLITE_CHANGESET_CONFLICT]. If this function ** is called on any other iterator, [SQLITE_MISUSE] is returned and *ppValue ** is set to NULL. ** ^*Argument iVal must be greater than or equal to 0, and less than the number ** of columns in the table affected by the current change. Otherwise, ** [SQLITE_RANGE] is returned and *ppValue is set to NULL.* ** ^*If successful, this function sets *ppValue to point to a protected ** sqlite3_value object containing the iVal'th value from the ** "conflicting row" associated with the current conflict-handler callback ** and returns SQLITE_OK.* ** ^*If some other error occurs (e.g. an OOM condition), an SQLite error code ** is returned and *ppValue is set to NULL.*

80874. **comment:** ** CAPI3REF: Unlock Notification ** METHOD: sqlite3 ** ** ^When running in shared-cache mode, a database operation may fail with ** an [SQLITE_LOCKED] error if the required locks on the shared-cache or ** individual tables within the shared-cache cannot be obtained. See ** [SQLite Shared-Cache Mode] for a description of shared-cache locking. ** ^This API may be used to register a callback that SQLite will invoke ** when the connection currently holding the required lock relinquishes it. ** ^This API is only available if the library was compiled with the ** [SQLITE_ENABLE_UNLOCK_NOTIFY] C-preprocessor symbol defined. ** ** See Also: [Using the SQLite Unlock Notification Feature]. ** ** ^Shared-cache locks are released when a database connection concludes ** its current transaction, either by committing it or rolling it back. ** ** ^When a connection (known as the blocked connection) fails to obtain a ** shared-cache lock and SQLITE_LOCKED is returned to the caller, the ** identity of the database connection (the blocking connection) that ** has locked the required resource is stored internally. ^After an ** application receives an SQLITE_LOCKED error, it may call the ** sqlite3_unlock_notify() method with the blocked connection handle as ** the first argument to register for a callback that will be invoked ** when the blocking connections current transaction is concluded. ^The ** callback is invoked from within the [sqlite3_step] or [sqlite3_close] ** call that concludes the blocking connections transaction. ** ** ^If sqlite3_unlock_notify() is called in a multi-threaded application, ** there is a chance that the blocking connection will have already ** concluded its transaction by the time sqlite3_unlock_notify() is invoked. ** If this happens, then the specified callback is invoked immediately, ** from within the call to sqlite3_unlock_notify().)^ ** ** ^If the blocked connection is attempting to obtain a write-lock on a ** shared-cache table, and more than one other connection currently holds ** a read-lock on the same table, then SQLite arbitrarily selects one of ** the other connections to use as the blocking connection. ** ** ^There may be at most one unlock-notify callback registered by a ** blocked connection. If sqlite3_unlock_notify() is called when the ** blocked connection already has a registered unlock-notify callback, ** then the new callback replaces the old.)^ ^If sqlite3_unlock_notify() is ** called with a NULL pointer as its second argument, then any existing ** unlock-notify callback is canceled. ^The blocked connections ** unlock-notify callback may also be canceled by closing the blocked ** connection using [sqlite3_close()]. ** ** ^The unlock-notify callback is not reentrant. If an application invokes ** any sqlite3_xxx API functions from within an unlock-notify callback, a ** crash or deadlock may be the result. ** ** ^Unless deadlock is detected (see below), sqlite3_unlock_notify() always ** returns SQLITE_OK. ** ** Callback Invocation Details ** ** When an unlock-notify callback is registered, the application provides a ** single void* pointer that is passed to the callback when it is invoked. ** However, the signature of the callback function allows SQLite to pass ** it an array of void* context pointers. The first argument passed to ** an unlock-notify callback is a pointer to an array of void* pointers, ** and the second is the number of entries in the array. ** ** When a blocking connections transaction is concluded, there may be ** more than one blocked connection that has registered for an unlock-notify ** callback. ^If two or more such blocked connections have specified the ** same callback function, then instead of invoking the callback function ** multiple times, it is invoked once with the set of void* context pointers ** specified by the blocked connections bundled together into an array. ** This gives the application an opportunity to prioritize any actions ** related to the set of unblocked database connections. ** ** Deadlock Detection ** ** Assuming that after registering for an unlock-notify callback a ** database waits for the callback to be issued before taking any further ** action (a reasonable assumption), then using this API may cause the ** application to deadlock. For example, if connection X is waiting for ** connection Y's transaction to be concluded, and similarly connection ** Y is waiting on connection X's transaction, then neither connection ** will proceed and the system may remain deadlocked indefinitely. ** ** To avoid this scenario, the sqlite3_unlock_notify() performs deadlock ** detection. ^If a given call to sqlite3_unlock_notify() would put the ** system in a deadlocked state, then SQLITE_LOCKED is returned and no ** unlock-notify callback is registered. The system is said to be in ** a deadlocked state if connection A has registered for an unlock-notify ** callback on the conclusion of connection B's transaction, and connection ** B has itself registered for an unlock-notify callback when connection ** A's transaction is concluded. ^Indirect deadlock is also detected, so ** the system is also considered to be deadlocked if connection B has ** registered for an unlock-notify callback on the conclusion of connection ** C's transaction, where connection C is waiting on connection A. ^Any ** number of levels of indirection are allowed. ** ** The "DROP TABLE" Exception ** ** When a call to [sqlite3_step()] returns SQLITE_LOCKED, it is almost ** always appropriate to call sqlite3_unlock_notify(). There is however, ** one exception. When executing a "DROP TABLE" or "DROP INDEX" statement, ** SQLite checks if there are any currently executing SELECT statements ** that belong to the same connection. If there are, SQLITE_LOCKED is ** returned. In this case there is no "blocking connection", so invoking ** sqlite3_unlock_notify() results in the unlock-notify callback being ** invoked immediately. If the application then re-attempts the "DROP TABLE" ** or "DROP INDEX" query, an infinite loop might be the result. ** ** One way around this problem is to check the extended error code returned ** by an sqlite3_step() call. ^If there is a blocking connection, then the ** extended error code is set to SQLITE_LOCKED_SHAREDCACHE. Otherwise, in ** the special "DROP TABLE/INDEX" case, the extended error code is just ** SQLITE_LOCKED.)^

80881. ** CAPI3REF: Generate A Changeset From A Session Object ** ** Obtain a changeset containing changes to the tables attached to the ** session object passed as the first argument. If successful, ** set *ppChangeset to point to a buffer containing the changeset ** and *pnChangeset to the size of the changeset in bytes before returning ** SQLITE_OK. If an error occurs, set both *ppChangeset and *pnChangeset to ** zero and return an SQLite error code. ** ** A changeset consists of zero or more INSERT, UPDATE and/or DELETE changes, ** each representing a change to a single row of an attached table. An INSERT ** change contains the values of each field of a new database row. A DELETE ** contains the original values of each field of a deleted database row. An ** UPDATE change contains the original values of each field of an updated ** database row along with the updated values for each updated non-primary-key ** column. It is not possible for an UPDATE change to represent a change that ** modifies the values of primary key columns. If such a change is made, it ** is represented in a changeset as a DELETE followed by an INSERT. ** ** Changes are not recorded for rows that have NULL values stored in one or ** more of their PRIMARY KEY columns. If such a row is inserted or deleted, ** no corresponding change is present in the changesets returned by this ** function. If an existing row with one or more NULL values stored in ** PRIMARY KEY columns is updated so that all PRIMARY KEY columns are non-NULL, ** only an INSERT is appears in the changeset. Similarly, if an existing row ** with non-NULL PRIMARY KEY values is updated so that one or more of its ** PRIMARY KEY columns are set to NULL, the resulting changeset contains a ** DELETE change only. ** ** The contents of a changeset may be traversed using an iterator created ** using the [sqlite3changeset_start()] API. A changeset may be applied to ** a database with a compatible schema using the [sqlite3changeset_apply()] ** API. ** ** Within a changeset generated by this function, all changes related to a ** single table are grouped together. In other words, when iterating through ** a changeset or when applying a changeset to a database, all changes related ** to a single table are processed before moving on to the next table. Tables ** are sorted in the same order in which they were attached (or auto-attached) ** to the sqlite3_session object. The order in which the changes related to ** a single table are stored is undefined. ** ** Following a successful call to this function, it is the responsibility of ** the caller to eventually free the buffer that *ppChangeset points to using ** [sqlite3_free()]. ** ** <h3>Changeset Generation</h3> ** ** Once a table has been attached to a session object, the session object ** records the primary key values of all new rows inserted into the table. ** It also records the original primary key and other column values of any ** deleted or updated rows. For each unique primary key value, data is only ** recorded once - the first time a row with said primary key is inserted, ** updated or deleted in the lifetime of the session. ** ** There is one exception to the previous paragraph: when a row is inserted, ** updated or deleted, if one or more of its primary key columns contain a ** NULL value, no record of the change is made. ** ** The session object therefore accumulates two types of records - those ** that consist of primary key values only (created when the user inserts ** a new record) and those that consist of the primary key values and the ** original values of other table columns (created

when the user deletes ** or updates a record). *** When this function is called, the requested changeset is created using ** both the accumulated records and the current contents of the database ** file. Specifically: *** ** For each record generated by an insert, the database is queried ** for a row with a matching primary key. If one is found, an INSERT ** change is added to the changeset. If no such row is found, no change ** is added to the changeset. *** For each record generated by an update or delete, the database is ** queried for a row with a matching primary key. If such a row is ** found and one or more of the non-primary key fields have been ** modified from their original values, an UPDATE change is added to ** the changeset. Or, if no such row is found in the table, a DELETE ** change is added to the changeset. If there is a row with a matching ** primary key in the database, but all fields contain their original ** values, no change is added to the changeset. ** *** This means, amongst other things, that if a row is inserted and then later ** deleted while a session object is active, neither the insert nor the delete ** will be present in the changeset. Or if a row is deleted and then later a ** row with the same primary key values inserted while a session object is ** active, the resulting changeset will contain an UPDATE change instead of ** a DELETE and an INSERT. *** When a session object is disabled (see the [sqlite3session_enable()] API), ** it does not accumulate records when rows are inserted, updated or deleted. ** This may appear to have some counter-intuitive effects if a single row ** is written to more than once during a session. For example, if a row ** is inserted while a session object is enabled, then later deleted while ** the same session object is disabled, no INSERT record will appear in the ** changeset, even though the delete took place while the session was disabled. ** Or, if one field of a row is updated while a session is disabled, and ** another field of the same row is updated while the session is enabled, the ** resulting changeset will contain an UPDATE change that updates both fields.

80887. ***** 3rd ***** 4th *****

80888. Database name or NULL

80889. ** CAPI3REF: Start a read transaction on an historical snapshot ** EXPERIMENTAL ** ^The [sqlite3_snapshot_open(D,S,P)] interface starts a ** read transaction for schema S of ** [database connection] D such that the read transaction ** refers to historical [snapshot] P, rather than the most ** recent change to the database. ** ^The [sqlite3_snapshot_open()] interface returns SQLITE_OK on success ** or an appropriate [error code] if it fails. *** ^In order to succeed, a call to [sqlite3_snapshot_open(D,S,P)] must be ** the first operation following the [BEGIN] that takes the schema S ** out of [autocommit mode]. ** ^In other words, schema S must not currently be in ** a transaction for [sqlite3_snapshot_open(D,S,P)] to work, but the ** database connection D must be out of [autocommit mode]. ** ^A [snapshot] will fail to open if it has been overwritten by a ** [checkpoint]. ** ^A call to [sqlite3_snapshot_open(D,S,P)] will fail if the ** database connection D does not know that the database file for ** schema S is in [WAL mode]. A database connection might not know ** that the database file is in [WAL mode] if there has been no prior ** I/O on that database connection, or if the database entered [WAL mode] ** after the most recent I/O on the database connection.)** (Hint: Run "[PRAGMA application_id]" against a newly opened ** database connection in order to make it ready to use snapshots.) *** The [sqlite3_snapshot_open()] interface is only available when the ** SQLITE_ENABLE_SNAPSHOT compile-time option is used.

80890. Copy of sixth arg to _apply()

80891. ** CAPI3REF: Set a table filter on a Session Object. ** The second argument (xFilter) is the "filter callback". For changes to rows ** in tables that are not attached to the Session object, the filter is called ** to determine whether changes to the table's rows should be tracked or not. ** If xFilter returns 0, changes is not tracked. Note that once a table is ** attached, xFilter will not be called again.

80892. ** CAPI3REF: Virtual Table Indexing Information ** KEYWORDS: sqlite3_index_info *** The sqlite3_index_info structure and its substructures is used as part ** of the [virtual table] interface to ** pass information into and receive the reply from the [xBestIndex] ** method of a [virtual table module]. The fields under **Inputs** are the ** inputs to xBestIndex and are read-only. xBestIndex inserts its ** results into the **Outputs** fields. *** ^The aConstraint[] array records WHERE clause constraints of the form: ** <blockquote>column OP expr</blockquote> ** where OP is =, <, <=, >, or >=.)^ ** ^The particular operator is ** stored in aConstraint[.].op using one of the ** [SQLITE_INDEX_CONSTRAINT_EQ | SQLITE_INDEX_CONSTRAINT_values].)^ ** ^The index of the column is stored in ** aConstraint[.].iColumn.^ ^((aConstraint[.].usable is TRUE if the ** expr on the right-hand side can be evaluated (and thus the constraint ** is usable) and false if it cannot.)^ ** ^The optimizer automatically inverts terms of the form "expr OP column" ** and makes other simplifications to the WHERE clause in an attempt to ** get as many WHERE clause terms into the form shown above as possible. ** ^The aConstraint[] array only reports WHERE clause terms that are ** relevant to the particular virtual table being queried. *** ^Information about the ORDER BY clause is stored in aOrderBy[]. ** ^Each term of aOrderBy records a column of the ORDER BY clause. ** ^The colUsed field indicates which columns of the virtual table may be ** required by the current scan. Virtual table columns are numbered from ** zero in the order in which they appear within the CREATE TABLE statement ** passed to sqlite3_declare_vtab(). For the first 63 columns (columns 0-62), ** the corresponding bit is set within the colUsed mask if the column may be ** required by SQLite. If the table has at least 64 columns and any column ** to the right of the first 63 is required, then bit 63 of colUsed is also ** set. In other words, column iCol may be required if the expression ** (colUsed & ((sqlite3_uint64)1 << (iCol>=63 ? 63 : iCol))) evaluates to ** non-zero. ** ^The [xBestIndex] method must fill aConstraintUsage[] with information ** about what parameters to pass to xFilter. ^If argvIndex>0 then ** the right-hand side of the corresponding aConstraint[] is evaluated ** and becomes the argvIndex-th entry in argv. ^((If aConstraintUsage[.].omit ** is true, then the constraint is assumed to be fully handled by the ** virtual table and is not checked again by SQLite.)^ ** ^The idxNum and idxPtr values are recorded and passed into the ** [xFilter] method. ** ^[sqlite3_free()] is used to free idxPrt if and only if ** needToFreeIdxPrt is true. ** ^The orderByConsumed means that output from [xFilter]/[xNext] will occur in ** the correct order to satisfy the ORDER BY clause so that no separate ** sorting step is required. *** ^The estimatedCost value is an estimate of the cost of a particular ** strategy. A cost of N indicates that the cost of the strategy is similar ** to a linear scan of an SQLite table with N rows. A cost of log(N) ** indicates that the expense of the operation is similar to that of a ** binary search on a unique indexed field of an SQLite table with N rows. ** ^The estimatedRows value is an estimate of the number of rows that ** will be returned by the strategy. *** ^The xBestIndex method may optionally populate the idxFlags field with a ** mask of SQLITE_INDEX_SCAN_* flags. Currently there is only one such flag - ** SQLITE_INDEX_SCAN_UNIQUE. If the xBestIndex method sets this flag, SQLite ** assumes that the strategy may visit at most one row. ** ^Additionally, if xBestIndex sets the SQLITE_INDEX_SCAN_UNIQUE flag, then ** SQLite also assumes that if a call to the xUpdate() method is made as ** part of the same statement to delete or update a virtual table row and the ** implementation returns SQLITE_CONSTRAINT, then there is no need to rollback ** any database changes. In other words, if the xUpdate() returns ** SQLITE_CONSTRAINT, the database contents must be exactly as they were ** before xUpdate was called. By contrast, if SQLITE_INDEX_SCAN_UNIQUE is not ** set and xUpdate returns SQLITE_CONSTRAINT, any database changes made by ** the xUpdate method are automatically rolled back by SQLite. ** ^IMPORTANT: The estimatedRows field was added to the sqlite3_index_info ** structure for SQLite [version 3.8.2] ([dateof:3.8.2]). ** If a virtual table extension is ** used with an SQLite version earlier than 3.8.2, the results of attempting ** to read or write the estimatedRows field are undefined (but are likely ** to included crashing the application). The estimatedRows field should ** therefore only be used if [sqlite3_libversion_number()] returns a ** value greater than or equal to 3008002. Similarly, the idxFlags field ** was added for [version 3.9.0] ([dateof:3.9.0]). ** It may therefore only be used if ** sqlite3_libversion_number() returns a value greater than or equal to ** 3009000.

The third argument ** to [sqlite3_trace_v2()] is an OR-ed combination of one or more of ** the following constants. ^The first argument to the trace callback ** is one of the following constants. *** ^New tracing constants may be added in future releases. *** ^A trace callback has four arguments: xCallback(T,C,P,X). ** ^The T argument is one of the integer type codes above. ** ^The C argument is a copy of the context pointer passed in as the ** fourth argument to [sqlite3_trace_v2()]. ** ^The P and X arguments are pointers whose meanings depend on T. *** <dl> ** [[SQLITE_TRACE_STMT]] <dt>SQLITE_TRACE_STMT</dt> ** <dd>^An SQLITE_TRACE_STMT callback is invoked when a prepared statement ** first begins running and possibly at other times during the ** execution of the prepared statement, such as at the start of each ** trigger subprogram. ^The P argument is a pointer to the ** [prepared statement]. ^The X argument is a pointer to a string which ** is the unexpanded SQL text of the prepared statement or an SQL comment ** that indicates the invocation of a trigger. ^The callback can compute ** the same text that would have been returned by the legacy [sqlite3_trace()] ** interface by using the X argument when X begins with "--" and invoking ** [sqlite3_expanded_sql(P)] otherwise. *** <dd>[[SQLITE_TRACE_PROFILE]] <dt>SQLITE_TRACE_PROFILE</dt> ** <dd>^An SQLITE_TRACE_PROFILE callback provides approximately the same ** information as is provided by the [sqlite3_profile()] callback. ** ^The P argument is a pointer to the [prepared statement] and the ** X argument points to a 64-bit integer which is the estimated of ** the number of nanosecond that the prepared statement took to run. ** ^The SQLITE_TRACE_PROFILE callback is invoked when the statement finishes. *** <dd>[[SQLITE_TRACE_ROW]] <dt>SQLITE_TRACE_ROW</dt> ** <dd>^An SQLITE_TRACE_ROW callback is invoked whenever a prepared ** statement generates a single row of result. ** ^The P argument is a pointer to the [prepared statement] and the ** X argument is unused. *** <dd>[[SQLITE_TRACE_CLOSE]] <dt>SQLITE_TRACE_CLOSE</dt> ** <dd>^An SQLITE_TRACE_CLOSE callback is invoked when a database ** connection closes. ** ^The P argument is a pointer to the [database connection] object ** and the X argument is unused. ** </dl>

80913. **comment:** ** CAPI3REF: Application Defined Page Cache. *** KEYWORDS: {page cache} *** ^The [sqlite3_config()][SQLITE_CONFIG_PCACHE2, ...] interface can ** register an alternative page cache implementation by passing in an ** instance of the sqlite3_pcache_methods2 structure. ^In many applications, most of the heap memory allocated by ** SQLite is used for the page cache. ** By implementing a ** custom page cache using this API, an application can better control ** the amount of memory consumed by SQLite, the way in which ** that memory is allocated and released, and the policies used to ** determine exactly which parts of a database file are cached and for ** how long. *** ^The alternative page cache mechanism is an ** extreme measure that is only needed by the most demanding applications. ** The built-in page cache is recommended for most uses. *** ^The contents of the sqlite3_pcache_methods2 structure are copied to an ** internal buffer by SQLite within the call to [sqlite3_config]. Hence ** the application may discard the parameter after the call to ** [sqlite3_config()] returns.)^ *** <dd>[[the xInit() page cache method]] ** ^The xInit() method is called once for each effective ** call to [sqlite3_initialize()]^ ** (usually only once during the lifetime of the process). ^The xInit() ** method is passed a copy of the sqlite3_pcache_methods2.pArg value.)^ ** The intent of the xInit() method is to set up global data structures ** required by the custom page cache implementation. ** ^If the xInit() method is NULL, then the ** built-in default page cache is used instead of the application defined ** page cache.)^ *** <dd>[[the xShutdown() page cache method]] ** ^The xShutdown() method is called by [sqlite3_shutdown()]. ** It can be used to clean up ** any outstanding resources before process shutdown, if required. ** ^The xShutdown() method may be NULL. *** ^SQLite automatically serializes calls to the xInit method, ** so the xInit method need not be threadsafe. ^The ** xShutdown method is only called from [sqlite3_shutdown()] so it does ** not need to be threadsafe either. All other methods must be threadsafe ** in multithreaded applications. *** ^SQLite will never invoke xInit() more than once without an intervening ** call to xShutdown(). *** <dd>[[the xCreate() page cache methods]] ** ^SQLite invokes the xCreate() method to construct a new cache instance. ** SQLite will typically create one cache instance for each open database file, ** though this is not guaranteed. ^The ** first parameter, szPage, is the size in bytes of the pages that must ** be allocated by the cache. ^szPage will always a power of two. ^The ** second parameter szExtra is a number of bytes of extra storage ** associated with each page cache entry. ^The szExtra parameter will ** a number less than 250. SQLite will use the ** extra szExtra bytes on each page to store metadata about the underlying ** database page on disk. The value passed into szExtra depends ** on the SQLite version, the target platform, and how SQLite was compiled. ** ^The third argument to xCreate(), bPurgeable, is true if the cache being ** created will be used to cache database pages of a file stored on disk, or ** false if it is used for an in-memory database. The cache implementation ** does not have to do anything special based with the value of bPurgeable; ** it is purely advisory. ^On a cache where bPurgeable is false, SQLite will ** never invoke xUnpin() except to deliberately delete a page. ** ^In other words, calls to xUnpin() on a cache with bPurgeable set to ** false will always have the "discard" flag set to true. ** ^Hence, a cache created with bPurgeable false will ** never contain any unpinned pages. *** <dd>[[the xCachesize() page cache method]] ** ^The xCachesize() method may be called at any time by SQLite to set the ** suggested maximum cache-size (number of pages stored by) the cache ** instance passed as the first argument. This is the value configured using ** the SQLite "[PRAGMA cache_size]" command.)^ As with the bPurgeable ** parameter, the implementation is not required to do anything with this ** value; it is advisory only. *** <dd>[[the xPagecount() page cache methods]] ** The xPagecount() method must return the number of pages currently ** stored in the cache, both pinned and unpinned. *** <dd>[[the xFetch() page cache methods]] ** The xFetch() method locates a page in the cache and returns a pointer to ** an sqlite3_pcache_page object associated with that page, or a NULL pointer. ** The pBuf element of the returned sqlite3_pcache_page object will be a ** pointer to a buffer of szPage bytes used to store the content of a ** single database page. The pExtra element of sqlite3_pcache_page will be ** a pointer to the szExtra bytes of extra storage that SQLite has requested ** for each entry in the page cache. *** ^The page to be fetched is determined by the key. ^The minimum key value ** is 1. After it has been retrieved using xFetch, the page is considered ** to be "pinned". *** ^If the requested page is already in the page cache, then the page cache ** implementation must return a pointer to the page buffer with its content ** intact. If the requested page is not already in the cache, then the ** cache implementation should use the value of the createFlag ** parameter to help it determined what action to take: *** <table border=1 width=85% align=center> ** <tr><th> createFlag </th> Behavior when page is not already in cache ** <tr><td> 0 </td> Do not allocate a new page. Return NULL. ** <tr><td> 1 </td> Allocate a new page if it easy and convenient to do so. ** Otherwise return NULL. ** <tr><td> 2 </td> Make every effort to allocate a new page. Only return ** NULL if allocating a new page is effectively impossible. ** </table> *** ^SQLite will normally invoke xFetch() with a createFlag of 0 or 1. SQLite ** will only use a createFlag of 2 after a prior call with a createFlag of 1 ** failed.)^ In between the to xFetch() calls, SQLite may ** attempt to unpin one or more cache pages by spilling the content of ** pinned pages to disk and synching the operating system disk cache. *** <dd>[[the xUnpin() page cache method]] ** ^xUnpin() is called by SQLite with a pointer to a currently pinned page ** as its second argument. If the third parameter, discard, is non-zero, ** then the page must be evicted from the cache. ** ^If the discard parameter is ** zero, then the page may be discarded or retained at the discretion of ** page cache implementation. ^The page cache implementation ** may choose to evict unpinned pages at any time. *** ^The cache must not perform any reference counting. A single ** call to xUnpin() unpins the page regardless of the number of prior calls ** to xFetch(). *** <dd>[[the xRekey() page cache methods]] ** The xRekey() method is used to change the key value associated with the ** page passed as the second argument. If the cache ** previously contains an entry associated with newKey, it must be ** discarded. ^Any prior cache entry associated with newKey is guaranteed not ** to be pinned. *** ^When SQLite calls the xTruncate() method, the cache must discard all ** existing cache entries with page numbers (keys) greater than or equal ** to the value of the iLimit parameter passed to xTruncate(). If any ** of these pages are pinned, they are implicitly unpinned, meaning that ** they can be safely discarded. *** <dd>[[the xDestroy() page cache method]] ** ^The xDestroy() method is used to delete a cache allocated by xCreate(). ** All resources associated with the specified cache should be freed. ^After ** calling the xDestroy() method, SQLite considers the [sqlite3_pcache*] ** handle invalid, and will not use it with any other sqlite3_pcache_methods2 **

functions. *** [[the xShrink() page cache method]] ** ^SQLite invokes the xShrink() method when it wants the page cache to ** free up as much of heap memory as possible. The page cache implementation ** is not obligated to free any memory, but well-behaved implementations should ** do their best.

label: code-design

80914. void*, int nByte, int min

80915. ** CAPI3REF: Database Snapshot ** KEYWORDS: {snapshot} {sqlite3_snapshot} ** EXPERIMENTAL ** ** An instance of the snapshot object records the state of a [WAL mode] ** database for some specific point in history. *** In [WAL mode], multiple [database connections] that are open on the ** same database file can each be reading a different historical version ** of the database file. When a [database connection] begins a read ** transaction, that connection sees an unchanging copy of the database ** as it existed for the point in time when the transaction first started. ** Subsequent changes to the database from other connections are not seen ** by the reader until a new read transaction is started. *** The sqlite3_snapshot object records state information about an historical ** version of the database file so that it is possible to later open a new read ** transaction that sees that historical version of the database rather than ** the most recent version. *** The constructor for this object is [sqlite3_snapshot_get()]. The ** [sqlite3_snapshot_open()] method causes a fresh read transaction to refer ** to an historical snapshot (if possible). The destructor for ** sqlite3_snapshot objects is [sqlite3_snapshot_free()].

80916. **comment:** ** CAPI3REF: Function Auxiliary Data ** METHOD: sqlite3_context ** ** These functions may be used by (non-aggregate) SQL functions to ** associate metadata with argument values. If the same value is passed to ** multiple invocations of the same SQL function during query execution, under ** some circumstances the associated metadata may be preserved. An example ** of where this might be useful is in a regular-expression matching ** function. The compiled version of the regular expression can be stored as ** metadata associated with the pattern string. ** Then as long as the pattern string remains the same, ** the compiled regular expression can be reused on multiple ** invocations of the same function. *** ^The sqlite3_get_auxdata(C,N) interface returns a pointer to the metadata ** associated by the sqlite3_set_auxdata(C,N,P,X) function with the Nth argument ** value to the application-defined function. ^N is zero for the left-most ** function argument. ^If there is no metadata ** associated with the function argument, the sqlite3_get_auxdata(C,N) interface ** returns a NULL pointer. *** ^The sqlite3_set_auxdata(C,N,P,X) interface saves P as metadata for the N-th ** argument of the application-defined function. ^Subsequent ** calls to sqlite3_get_auxdata(C,N) return P from the most recent ** sqlite3_set_auxdata(C,N,P,X) call if the metadata is still valid or ** NULL if the metadata has been discarded. ** ^After each call to sqlite3_set_auxdata(C,N,P,X) where X is not NULL, ** SQLite will invoke the destructor function X with parameter P exactly ** once, when the metadata is discarded. ** SQLite is free to discard the metadata at any time, including: ** ^when the corresponding function parameter changes)^, or ** ^when [sqlite3_reset()] or [sqlite3_finalize()] is called for the ** SQL statement)^, or ** ^when sqlite3_set_auxdata() is invoked again on the same ** parameter)^, or ** ^during the original sqlite3_set_auxdata() call when a memory ** allocation error occurs.^ *** Note the last bullet in particular. The destructor X in ** sqlite3_set_auxdata(C,N,P,X) might be called immediately, before the ** sqlite3_set_auxdata() interface even returns. Hence sqlite3_set_auxdata() ** should be called near the end of the function implementation and the ** function implementation should not make any use of P after ** sqlite3_set_auxdata() has been called. *** ^In practice, metadata is preserved between function calls for ** function parameters that are compile-time constants, including literal ** values and [parameters] and expressions composed from the same.)^ *** ^The value of the N parameter to these interfaces should be non-negative. ** Future enhancements may make use of negative N values to define new ** kinds of function caching behavior. *** ^These routines must be called from the same thread in which ** the SQL function is running.

80935. ** CAPI3REF: Concatenate Two Changeset Objects ** ** This function is used to concatenate two changesets, A and B, into a ** single changeset. The result is a changeset equivalent to applying ** changeset A followed by changeset B. *** This function combines the two input changesets using an ** sqlite3_changegroup object. Calling it produces similar results as the ** following code fragment: *** ** sqlite3_changegroup *pGrp; ** rc = sqlite3_changegroup_new(&pGrp); ** if(rc==SQLITE_OK) rc = sqlite3changegroup_add(pGrp, nA, pA); ** if(rc==SQLITE_OK) rc = sqlite3changegroup_add(pGrp, nB, pB); ** if(rc==SQLITE_OK){ ** rc = sqlite3changegroup_output(pGrp, pnOut, ppOut); ** }else{ ** ppOut = 0; ** *pnOut = 0; ** } *** Refer to the sqlite3_changegroup documentation below for details.

80936. ** CAPI3REF: Checkpoint a database ** METHOD: sqlite3 ** ** ^The sqlite3_wal_checkpoint(D,X) is equivalent to ** [sqlite3_wal_checkpoint_v2](D,X, [SQLITE_CHECKPOINT_PASSIVE],0,0).)*** ^In brief, sqlite3_wal_checkpoint(D,X) causes the content in the ** [write-ahead log] for database X on [database connection] D to be ** transferred into the database file and for the write-ahead log to ** be reset. See the [checkpointing] documentation for addition ** information. *** ^This interface used to be the only way to cause a checkpoint to ** occur. But then the newer and more powerful [sqlite3_wal_checkpoint_v2] ** interface was added. This interface is retained for backwards ** compatibility and as a convenience for applications that need to manually ** start a callback but which do not need the full power (and corresponding ** complication) of [sqlite3_wal_checkpoint_v2].

80937. ***** End of sqlite3session.h *****

80938. ** CAPI3REF: Set the Last Insert Rowid value. ** METHOD: sqlite3 ** ** The sqlite3_set_last_insert_rowid(D, R) method allows the application to ** set the value returned by calling sqlite3_last_insert_rowid(D) to R ** without inserting a row into the database.

80939. ** CAPI3REF: Mutex Verification Routines ** ** The sqlite3_mutex_held() and sqlite3_mutex_noheld() routines ** are intended for use inside assert() statements. The SQLite core ** never uses these routines except inside an assert() and applications ** are advised to follow the lead of the core. The SQLite core only ** provides implementations for these routines when it is compiled ** with the SQLITE_DEBUG flag. External mutex implementations ** are only required to provide these routines if SQLITE_DEBUG is ** defined and if NDEBUG is not defined. *** ^These routines should return true if the mutex in their argument ** is held or not held, respectively, by the calling thread. *** ^The implementation is not required to provide versions of these ** routines that actually work. If

the implementation does not provide working ** versions of these routines, it should at least provide stubs that always ** return true so that one does not get spurious assertion failures. *** If the argument to sqlite3_mutex_held() is a NULL pointer then ** the routine should return 1. This seems counter-intuitive since ** clearly the mutex cannot be held if it does not exist. But ** the reason the mutex does not exist is because the build is not ** using mutexes. And we do not want the assert() containing the ** call to sqlite3_mutex_held() to fail, so a non-zero return is ** the appropriate thing to do. The sqlite3_mutex_notheld() ** interface should also return 1 when given a NULL pointer.

80940. ** Make sure we can call this stuff from C++.

80941. ** CAPI3REF: Flags for the xShmLock VFS method *** These integer constants define the various locking operations ** allowed by the xShmLock method of [sqlite3_io_methods]. The ** following are the only legal combinations of flags to the ** xShmLock method: *** ** SQLITE_SHM_LOCK | SQLITE_SHM_SHARED ** SQLITE_SHM_LOCK | SQLITE_SHM_EXCLUSIVE ** SQLITE_SHM_UNLOCK | SQLITE_SHM_SHARED ** SQLITE_SHM_UNLOCK | SQLITE_SHM_EXCLUSIVE ** *** When unlocking, the same SHARED or EXCLUSIVE flag must be supplied as ** was given on the corresponding lock. *** The xShmLock method can transition between unlocked and SHARED or ** between unlocked and EXCLUSIVE. It cannot transition between SHARED ** and EXCLUSIVE.

80942. Deprecated

80943. ** CAPI3REF: String Comparison *** ^The [sqlite3_stricmp()] and [sqlite3_strnicmp()] APIs allow applications ** and extensions to compare the contents of two buffers containing UTF-8 ** strings in a case-independent fashion, using the same definition of "case ** independence" that SQLite uses internally when comparing identifiers.

80976. comment: ** CAPI3REF: Advance A Changeset Iterator ** ** This function may only be used with iterators created by function ** [sqlite3changeset_start()]. If it is called on an iterator passed to ** a conflict-handler callback by [sqlite3changeset_apply()], SQLITE_MISUSE ** is returned and the call has no effect. ** ** Immediately after an iterator is created by sqlite3changeset_start(), it ** does not point to any change in the changeset. Assuming the changeset ** is not empty, the first call to this function advances the iterator to ** point to the first change in the changeset. Each subsequent call advances ** the iterator to point to the next change in the changeset (if any). If ** no error occurs and the iterator points to a valid change after a call ** to sqlite3changeset_next() has advanced it, SQLITE_ROW is returned. ** Otherwise, if all changes in the changeset have already been visited, ** SQLITE_DONE is returned. ** ** If an error occurs, an SQLite error code is returned. Possible error ** codes include SQLITE_CORRUPT (if the changeset buffer is corrupt) or ** SQLITE_NOMEM.

label: code-design

80977. ** CAPI3REF: Compile-Time Authorization Callbacks ** METHOD: sqlite3 ** KEYWORDS: {authorizer callback} ** ** ^This routine registers an authorizer callback with a particular ** [database connection], supplied in the first argument. ** ^The authorizer callback is invoked as SQL statements are being compiled ** by [sqlite3_prepare()] or its variants [sqlite3_prepare_v2()], ** [sqlite3_prepare_v3()], [sqlite3_prepare160], [sqlite3_prepare16_v2()], ** and [sqlite3_prepare16_v3()]. ^At various ** points during the compilation process, as logic is being created ** to perform various actions, the authorizer callback is invoked to ** see if those actions are allowed. ^The authorizer callback should ** return [SQLITE_OK] to allow the action, [SQLITE_IGNORE] to disallow the ** specific action but allow the SQL statement to continue to be ** compiled, or [SQLITE_DENY] to cause the entire SQL statement to be ** rejected with an error. ^If the authorizer callback returns ** any value other than [SQLITE_IGNORE], [SQLITE_OK], or [SQLITE_DENY] ** then the [sqlite3_prepare_v2()] or equivalent call that triggered ** the authorizer will fail with an error message. ** ** ^When the callback returns [SQLITE_OK], that means the operation ** requested is ok. ^When the callback returns [SQLITE_DENY], the ** [sqlite3_prepare_v2()] or equivalent call that triggered the ** authorizer will fail with an error message explaining that ** access is denied. ** ** ^The first parameter to the authorizer callback is a copy of the third ** parameter to the sqlite3_set_authorizer() interface. ^The second parameter ** to the callback is an integer [SQLITE_COPY | action code] that specifies ** the particular action to be authorized. ^The third through sixth parameters ** to the callback are either NULL pointers or zero-terminated strings ** that contain additional details about the action to be authorized. ** Applications must always be prepared to encounter a NULL pointer in any ** of the third through the sixth parameters of the authorization callback. ** ** ^If the action code is [SQLITE_READ] ** and the callback returns [SQLITE_IGNORE] then the ** [prepared statement] statement is constructed to substitute ** a NULL value in place of the table column that would have ** been read if [SQLITE_OK] had been returned. The [SQLITE_IGNORE] ** return can be used to deny an untrusted user access to individual ** columns of a table. ** ^When a table is referenced by a [SELECT] but no column values are ** extracted from that table (for example in a query like ** "SELECT count(*) FROM tab") then the [SQLITE_READ] authorizer callback ** is invoked once for that table with a column name that is an empty string. ** ^If the action code is [SQLITE_DELETE] and the callback returns ** [SQLITE_IGNORE] then the [DELETE] operation proceeds but the ** [truncate optimization] is disabled and all rows are deleted individually. ** ** An authorizer is used when [sqlite3_prepare | preparing] ** SQL statements from an untrusted source, to ensure that the SQL statements ** do not try to access data they are not allowed to see, or that they do not ** try to execute malicious statements that damage the database. For ** example, an application may allow a user to enter arbitrary ** SQL queries for evaluation by a database. But the application does ** not want the user to be able to make arbitrary changes to the ** database. An authorizer could then be put in place while the ** user-entered SQL is being [sqlite3_prepare | prepared] that ** disallows everything except [SELECT] statements. ** ** Applications that need to process SQL from untrusted sources ** might also consider lowering resource limits using [sqlite3_limit()] ** and limiting database size using the [max_page_count] [PRAGMA] ** in addition to using an authorizer. ** ** ^Only a single authorizer can be in place on a database connection ** at a time. Each call to sqlite3_set_authorizer overrides the ** previous call.)^ ^Disable the authorizer by installing a NULL callback. ** The authorizer is disabled by default. ** ** The authorizer callback must not do anything that will modify ** the database connection for the meaning of "modify" in this paragraph. ** ** ^When [sqlite3_prepare_v2()] is used to prepare a statement, the ** statement might be re-prepared during [sqlite3_step()] due to a ** schema change. Hence, the application should ensure that the ** correct authorizer callback remains in place during the [sqlite3_step()]. ** ** ^Note that the authorizer callback is invoked only during ** [sqlite3_prepare()] or its variants. Authorization is not ** performed during statement evaluation in [sqlite3_step()], unless ** as stated in the previous paragraph, sqlite3_step() invokes ** sqlite3_prepare_v2() to reprepare a statement after a schema change.

80980. NULL NULL
80981. Authorization denied
80982. OUT: Statement handle
80983. ** CAPI3REF: Create A New Session Object *** Create a new session object attached to database handle db. If successful, ** a pointer to the new object is written to *ppSession and SQLITE_OK is ** returned. If an error occurs, *ppSession is set to NULL and an SQLite ** error code (e.g. SQLITE_NOMEM) is returned. *** It is possible to create multiple session objects attached to a single ** database handle. *** Session objects created using this function should be deleted using the ** [sqlite3session_delete()] function before the database handle that they ** are attached to is itself closed. If the database handle is closed before ** the session object is deleted, then the results of calling any session ** module function, including [sqlite3session_delete()] on the session object ** are undefined. *** Because the session module uses the [sqlite3_preupdate_hook()] API, it ** is not possible for an application to register a pre-update hook on a ** database handle that has one or more session objects attached. Nor is ** it possible to create a session object attached to a database handle for ** which a pre-update hook is already defined. The results of attempting ** either of these things are undefined. *** The session object will be used to create changesets for tables in ** database zDb, where zDb is either "main", or "temp", or the name of an ** attached database. It is not an error if database zDb is not attached ** to the database when the session object is created.
80984. ** CAPI3REF: Deprecated Soft Heap Limit Interface *** DEPRECATED *** This is a deprecated version of the [sqlite3_soft_heap_limit64()] ** interface. This routine is provided for historical compatibility ** only. All new applications should use the ** [sqlite3_soft_heap_limit64()] interface rather than this one.
80985. Context passed to xToken()
80986. Deinitialize the memory allocator
80987. ** CAPI3REF: Close A BLOB Handle ** DESTRUCTOR: sqlite3_blob *** ^This function closes an open [BLOB handle]. ^The BLOB handle is closed ** unconditionally. Even if this routine returns an error code, the ** handle is still closed.^ ** ^If the blob handle being closed was opened for read-write access, and if ** the database is in auto-commit mode and there are no other open read-write ** blob handles or active write statements, the current transaction is ** committed. ^If an error occurs while committing the transaction, an error ** code is returned and the transaction rolled back. *** Calling this function with an argument that is not a NULL pointer or an ** open blob handle results in undefined behaviour. ^Calling this routine ** with a null pointer (such as would be returned by a failed call to ** [sqlite3_blob_open()]) is a harmless no-op. ^Otherwise, if this function ** is passed a valid open blob handle, the values returned by the ** sqlite3_errcode() and sqlite3errmsg() functions are set before returning.
80988. ** CAPI3REF: Write-Ahead Log Commit Hook ** METHOD: sqlite3 *** ^The [sqlite3_wal_hook()] function is used to register a callback that ** is invoked each time data is committed to a database in wal mode. *** ^The callback is invoked by SQLite after the commit has taken place and ** the associated write-lock on the database released^, so the implementation ** may read, write or [checkpoint] the database as required. *** ^The first parameter passed to the callback function when it is invoked ** is a copy of the third parameter passed to sqlite3_wal_hook() when ** registering the callback. ^The second is a copy of the database handle. ** ^The third parameter is the name of the database that was written to - ** either "main" or the name of an [ATTACH]-ed database. ^The fourth parameter ** is the number of pages currently in the write-ahead log file, ** including those that were just committed. *** ^The callback function should normally return [SQLITE_OK]. ^If an error ** code is returned, that error will propagate back up through the ** SQLite code base to cause the statement that provoked the callback ** to report an error, though the commit will have still occurred. If the ** callback returns [SQLITE_ROW] or [SQLITE_DONE], or if it returns a value ** that does not correspond to any valid SQLite error code, the results ** are undefined. *** ^A single database handle may have at most a single write-ahead log callback ** registered at one time. ^Calling [sqlite3_wal_hook()] replaces any ** previously registered write-ahead log callback. ^Note that the ** [sqlite3_wal_autocheckpoint()] interface and the ** [wal_autocheckpoint pragma] both invoke [sqlite3_wal_hook()] and will ** overwrite any prior [sqlite3_wal_hook()] settings.
80989. **comment:** ** CAPI3REF: Suspend Execution For A Short Time *** The sqlite3_sleep() function causes the current thread to suspend execution ** for at least a number of milliseconds specified in its parameter. *** ^If the operating system does not support sleep requests with ** millisecond time resolution, then the time will be rounded up to ** the nearest second. The number of milliseconds of sleep actually ** requested from the operating system is returned. *** ^SQLite implements this interface by calling the xSleep() ** method of the default [sqlite3_vfs] object. If the xSleep() method ** of the default VFS is not implemented correctly, or not implemented at ** all, then the behavior of sqlite3_sleep() may deviate from the description ** in the previous paragraphs.

81009. Input: Mask of columns used by statement

81010. ** CAPI3REF: Number of columns in a result set ** METHOD: sqlite3_stmt *** ^The sqlite3_data_count(P) interface returns the number of columns in the ** current row of the result set of [prepared statement] P. ** ^If prepared statement P does not have results ready to return ** (via calls to the [sqlite3_column_int | sqlite3_column_*] of ** interfaces) then sqlite3_data_count(P) returns 0. ** ^The sqlite3_data_count(P) routine also returns 0 if P is a NULL pointer. ** ^The sqlite3_data_count(P) routine returns 0 if the previous call to ** [sqlite3_step](P) returned [SQLITE_DONE]. ^The sqlite3_data_count(P) ** will return non-zero if previous call to [sqlite3_step](P) returned ** [SQLITE_ROW], except in the case of the [PRAGMA incremental_vacuum] ** where it always returns zero since each step of that multi-step ** pragma returns 0 columns of data. ** See also: [sqlite3_column_count()]

81011. Handle describing change and conflict

81012. **comment:** ** CAPI3REF: Define New Collating Sequences ** METHOD: sqlite3 *** ^These functions add, remove, or modify a [collation] associated ** with the [database connection] specified as the first argument. ** ^The name of the collation is a UTF-8 string ** for sqlite3_create_collation()

sqlite3_create_collation_v2() ** and a UTF-16 string in native byte order for sqlite3_create_collation16(). ** ^Collation names that compare equal according to [sqlite3_strnicmp()] are ** considered to be the same name. ** ** ^The third argument (eTextRep) must be one of the constants: ** ** [SQLITE_UTF8], ** [SQLITE_UTF16LE], ** [SQLITE_UTF16BE], ** [SQLITE_UTF16], or ** [SQLITE_UTF16_ALIGNED]. **)^ ** ^The eTextRep argument determines the encoding of strings passed ** to the collating function callback, xCallback. ** ^The [SQLITE_UTF16] and [SQLITE_UTF16_ALIGNED] values for eTextRep ** force strings to be UTF16 with native byte order. ** ^The [SQLITE_UTF16_ALIGNED] value for eTextRep forces strings to begin ** on an even byte address. ** ** ^The fourth argument, pArg, is an application data pointer that is passed ** through as the first argument to the collating function callback. ** ** ^The fifth argument, xCallback, is a pointer to the collating function. ** ^Multiple collating functions can be registered using the same name but ** with different eTextRep parameters and SQLite will use whichever ** function requires the least amount of data transformation. ** ^If the xCallback argument is NULL then the collating function is ** deleted. ^When all collating functions having the same name are deleted, ** that collation is no longer usable. ** ** ^The collating function callback is invoked with a copy of the pArg ** application data pointer and with two strings in the encoding specified ** by the eTextRep argument. The collating function must return an ** integer that is negative, zero, or positive ** if the first string is less than, equal to, or greater than the second, ** respectively. A collating function must always return the same answer ** given the same inputs. If two or more collating functions are registered ** to the same collation name (using different eTextRep values) then all ** must give an equivalent answer when invoked with equivalent strings. ** The collating function must obey the following properties for all ** strings A, B, and C: ** ** ** If A==B then B==A. ** If A==B and B==C then A==C. ** If A<B THEN B>A. ** If A<B and B<C then A<C. ** ** ** If a collating function fails any of the above constraints and that ** collating function is registered and used, then the behavior of SQLite ** is undefined. ** ** ^The sqlite3_create_collation_v20 works like sqlite3_create_collation() ** with the addition that the xDestroy callback is invoked on pArg when ** the collating function is deleted. ** ^Collating functions are deleted when they are overridden by later ** calls to the collation creation functions or when the ** [database connection] is closed using [sqlite3_close()]. ** ** ^The xDestroy callback is <u>not</u> called if the ** sqlite3_create_collation_v2() function fails. Applications that invoke ** sqlite3_create_collation_v2() with a non-NULL xDestroy argument should ** check the return code and dispose of the application data pointer ** themselves rather than expecting SQLite to deal with it for them. ** This is different from every other SQLite interface. The inconsistency ** is unfortunate but cannot be changed without breaking backwards ** compatibility. ** ** See also: [sqlite3_collation_needed()] and [sqlite3_collation_needed16()].

81126. req7 is invalid, but not yet complete

81127. a million "a" in blocks of 10

81128. Same is true for a leading space

81129. Used to debug test cases without using the check framework

81130. **comment:** TODO: adapt test for big endian81130. **label:** test

81131. req8 is a valid response

81132. **comment:** Pass small buffer, make sure alloc_printf allocates
label: code-design

81133. req2 is a complete, but invalid request

81134. a million "a"

81135. An empty string is neither a complete request nor a complete * response, so it must return 0

81136. Test alternative implementation

81137. is_valid_uri is superseeded by get_uri_type

81138. req11 is a complete but valid request

81139. length without body

81140. req9 is a valid response

81141. Valid request

81142. **comment:** TODO: check this for big endian
label: requirement

81143. **comment:** Can not test, if SHA1 is not included
label: test

81144. But a control character (like 0) makes it invalid

81145. req6 is incomplete

81146. req1 minus 1 byte at the start is complete but invalid

81147. Copyright (c) 2013-2015 the Civetweb developers

81148. test_parse_port_string requires WSASStartup for IPv6

81149. empty string

81150. "abc"

81151. part of "Thu, 01 Jan 1970 00:00:00 GMT"

81152. If the string is truncated, mg_snprintf calls mg_cry. * If DEBUG is defined, mg_cry calls DEBUG_TRACE. * In DEBUG_TRACE_FUNC, flockfile(stdout) is called. * For Windows, flockfile/funlockfile calls Enter-/ * LeaveCriticalSection(&global_log_file_lock). * So, we need to initialize global_log_file_lock:

81189. return 0 to accept every connection
81190. HTTP 1.1 GET request
81191. Read file before a .htpasswd file has been created
81192. This test should ensure the minimum server example in * docs/Embedding.md is still running.
81193. send some kilobyte of data
81194. TODO: fix path in CI test environment
81195. Can not send a websocket goodbye message here - * the connection is already closed
81196. Get data from callback using https://127.0.0.1
81197. Remove log files (they may exist from previous incomplete runs of * this test)
81198. TODO: ck_assert_str_eq(client_ri->request_method, "HTTP/1.0");
81199. Handle form: "POST x-www-form-urlencoded"
81200. Repeat test after .htpasswd is created
81201. Set options and start server
81202. Ask for something not existing - should get error404.htm
81203. Websocket test
81204. Elapsed time in ms - in most systems * only with second resolution
81205. www.github.com
81206. Stop the server
81207. Disconnect client 3
81208. Server start parameters for HTTPS
81209. HTTPS port - required
81210. Call a test client
81211. This unit test file uses the excellent Check unit testing library. * The API documentation is available here: * http://check.sourceforge.net/doc/check_html/index.html
81212. Wait for the websocket acknowledgement message
81213. defined(MG_USE_OPEN_FILE)
81214. set minimum SSL version to TLS 1.2 - recommended
81215. TODO: Check this problem on AppVeyor ck_assert_int_le(retry_fail_cnt, 2); ck_assert_int_ge(retry_ok_cnt, 1);
81216. Ask in a malformed way - should get error4xx.htm
81217. set "HTTPS only" header - recommended
81218. timing test
81219. Start server with bad options
81220. Try to copy the files required for AppVeyor
81221. Connect client 4
81222. not authorized
81223. **comment:** Stop the server and clean up
 label: code-design
81224. Handle form: "POST multipart/form-data" with chunked transfer encoding
81225. HTTP 1.1 GET request - must not work, since server is already stopped
81226. Client data
81227. return 1 to keep the connection open
81228. **comment:** Remove log files
 label: code-design
81229. e.g.: ck_assert_str_eq(client_ri->request_uri, "200");
81230. Return 1 means "already handled"
81231. strlen(websocket_goodbye_msg)
81232. Handle form: "POST multipart/form-data", chunked, store
81233. **comment:** Time estimation: Data size is 10 kB, with 1 kB/s speed limit. * The first block (1st kB) is transferred immediately, the second * block (2nd kB) one second later, the third block (3rd kB) two * seconds later, .. the last block (10th kB) nine seconds later. * The resolution of time measurement using the "time" C library * function is 1 second, so we should add +/- one second tolerance. * Thus, download of 10 kB with 1 kB/s should not be faster than * 8 seconds.
 label: code-design
81234. Free test data
81235. Response must be 505 HTTP Version not supported
81236. Error replies will close the connection, even if keep-alive is set.
81237. Get CGI generated data
81238. Try to access the file again. Expected: 401 error
81239. Response must be 400 Bad Request
81240. Try downloading several times
81241. full length string compare will reach limit in the implementation * of the check unit test framework
81242. Ask for something not existing - should get error4xx.htm
81243. Don't need to do this if mg_start failed
81244. Used to debug test cases without using the check framework
81245. Get directory listing
81246. Get data from callback
81247. Check error.log
81248. set some modern ciphers - recommended
81249. Get data from callback using mg_connect_client instead of mg_download
81250. Create an error4xx.htm file
81251. The check unit test library does not have build in memcmp functions.

81252. Start with default options
81253. It seems to be impossible to find out what the actual working * directory of the CI test environment is. Before breaking another * dozen of builds by trying blindly with different paths, just * create the file here
81254. File is in memory
81255. **comment:** TODO: add test for windows, check with POST
label: test
81256. *****
81257. Do not set this on Travis CI, since the build containers * contain older SSL libraries
81258. Build command for Linux: gcc test/public_server.c src/civetweb.c -I include/ -I test/ -l pthread -l dl -D LOCAL_TEST -D REPLACE_CHECK_FOR_LOCAL_DEBUGGING -D MAIN_PUBLIC_SERVER=main
81259. **comment:** TODO: the different paths * used in the different test * system is an unsolved * problem.
label: test
81260. Set to a number - but use a number above the limit
81261. Connect client 3
81262. chunks from 1 byte to strlen(boundary)-1
81263. File content check var
81264. Filename is required
81265. Response must be 200 OK
81266. Server var
81267. ck_assert_int_eq(i, (int)strlen(expected_cgi_result));
81268. **comment:** Remove invalid option
label: code-design
81269. Debug output for tests
81270. Handle form: "POST multipart/form-data", chunked, store, with files
81271. Get zipped static data - with Accept-Encoding
81272. assume there is enough space left in our typical 255 character string buffers
81273. Try to load non existing file
81274. Write long data (16 bit size header)
81275. Run the server for 15 seconds
81276. Get the current working directory
81277. Server context handle
81278. PUT to static file (will not work)
81279. We don't need the original anymore, the server has a private copy
81280. Get data from callback using https://[::1]
81281. Get data from callback using http://127.0.0.1
81282. strlen(websocket_welcome_msg)
81283. **comment:** TODO: A client API using a client certificate is missing
label: code-design
81284. stop the server without closing this connection
81285. Call the form handler
81286. Check the test dir
81287. First test with GET
81288. Handle form: "POST x-www-form-urlencoded", chunked, store
81289. HTTP 1.7 GET request - this HTTP version does not exist
81290. Initialize the library
81291. Start the server
81292. File is not in memory
81293. path to certificate file - required
81294. nonce is from including (auth_request + len) to excluding (str)
81295. Remove error files (in case they exist)
81296. Ask for something not existing - should get error.htm
81297. Not a valid HTTP response code, * but it should be written to the log and passed to * end_request.
81298. Add some handler
81299. Get redirect from callback using http://127.0.0.1
81300. CGI_ENVIRONMENT_SIZE
81301. Wait for the response
81302. Add large env field, so the server * must reallocate buffers.
81303. This time start the server with a valid configuration
81304. Create an error.htm file
81305. Retry DELETE with authorization of a user not authorized for DELETE
81306. Abort test with diagnostic message
81307. Ask for something not existing - should get default 404
81308. USE_WEBSOCKET
81309. Travis
81310. Read PUT response
81311. The Linux builds on Travis CI work fine with TLS1.2
81312. Send websocket welcome message
81313. HTTP request with multiline header. * Multiline header are obsolete with RFC 7230 section-3.2.4 * and must return "400 Bad Request"
81314. __MACH__
81315. Access to the file must work like before
81316. Get data from callback using mg_connect_client and absolute URI with a * sub-domain
81317. Check if there are at least 8 seconds
81318. **comment:** not required
label: requirement
81319. Create an error404.htm file
81320. WEBSOCKET SERVER
81321. This test should show a HTTPS server with enhanced * security settings. * * Articles: * <https://hynek.me/articles/hardening-your-web-servers-ssl-ciphers/> * * Scanners: * <https://securityheaders.io/> * <https://www.htbridge.com/ssl/> * <https://www.htbridge.com/websec/> * <https://www.ssllabs.com/ssltest/> * <https://www.qualys.com/forms/freescan/>
81322. test with unknown option
81323. Get zipped static data - will not work if Accept-Encoding is not set
81324. Check if CGI test executable exists
81325. **comment:** Return codes of the tested functions are evaluated. Checking all other * functions, used only to prepare the test environment seems redundant. * If they fail, the test fails anyway.
label: code-design
81326. Handle form: "POST multipart/form-data"
81327. HTTP 1.0 GET request
81328. Get data from callback using mg_connect_client and absolute URI

81329. For unknown reasons, there are sporadic hangs * for OSX if mark_point is called here
81330. Now connect a second client
81331. Create a default file in the document root
81332. Give the server some time to start in the test VM
81333. Won't get any message
81334. Then connect a first client
81335. Check access.log
81336. Closed
81337. Prepare test data
81338. Test with CGI test executable
81339. Now test form_store
81340. Un-initialize the library
81341. breakpoint here !
81342. Close the server
81343. **comment:** Copy the untruncated value, so string compare functions can be used.
 label: code-design
81344. method not allowed
81345. **comment:** TODO: request a file and keep alive * (will only work if NO_FILES is not set).
 label: code-design
81346. First store the length information in a text buffer.
81347. Create a .htpasswd file
81348. Server is running now
81349. **comment:** TODO: not yet available
 label: requirement
81350. Write long data (64 bit size header)
81351. Remove the user from the .htpasswd file again
81352. Wait for the websocket goodbye message
81353. sending megabytes to localhost does not always work in CI test * environments (depending on the network stack)
81354. send some strings that are almost boundaries
81355. Get static data
81356. Appveyor
81357. 81445. Have deleter which will erase item from cache, which will re-enter the cache at that point.

81446. release remaining 5 to keep valgrind happy
81447. cache is under capacity now since elements were released
81448. test1: increase capacity lets create a cache with capacity 5, then, insert 5 elements, then increase capacity to 10, returned capacity should be 10, usage=5
81449. the cache is over capacity since nothing could be evicted
81450. delete the key from the cache
81451. Add a bunch of light and heavy entries and then count the combined size of items still in the cache, which must be approximately the same as the total capacity.
81452. Insert item large than capacity to trigger eviction on empty cache.
81453. **comment:** Cleaning up all the handles
 label: code-design
81454. First release (i == 1) corresponds to Ref(), second release (i == 2) corresponds to Lookup(). Then, since all external refs are released, the below insertions should push out the cache entry.
81455. namespace rocksdb
81456. This tests that deleter is not called. When cache has free capacity it is not expected to immediately erase the released items.
81457. test3: init with flag being true.
81458. AS if the key have been inserted into cache but get evicted immediately.
81459. Frequently used entry must be kept around
81460. SUPPORT_CLOCK_CACHE
81461. test2: decrease capacity insert 5 more elements to cache, then release 5, then decrease capacity to 7, final capacity should be 7 and usage should be 7
81462. **comment:** cache is shared_ptr and will be automatically cleaned up.
 label: code-design
81463. namespace
81464. test1: set the flag to false. Insert more keys than capacity. See if they all go through.
81465. If i % 2 == 0, then the entry was unpinned before Lookup, so pinned usage increased
81466. the usage should be close to the capacity
81467. Check whether the entries inserted in the beginning are evicted. Ones without extra ref are evicted and those with are not.
81468. make sure the cache will be overloaded
81469. test insert without handle
81470. **comment:** release handles for pinned entries to prevent memory leaks
 label: code-design
81471. can no longer find in the cache
81472. Add entries. Unpin some of them after insertion. Then, pin some of them again. Check GetPinnedUsage().
81473. Guess what's in the cache now?
81474. This tests that deleter has been called
81475. Make sure eviction is triggered.
81476. Insert 5 entries, but not releasing.
81477. Insert n+1 entries, but not releasing.
81478. double cache size because the usage bit in block cache prevents 100 from being evicted in the first kCacheSize iterations
81479. a LRU Cache with n entries and one shard only
81480. release one handle
81481. test2: set the flag to true. Insert and check if it fails.
81482. Conversions between numeric keys/values and the types expected by Cache.
81483. Insert entries much more than Cache capacity
81484. element 0 is evicted and the rest is there This is consistent with the LRU policy since the element 0 was released first
81485. check that overloading the cache does not change the pinned usage
81486. insert a key and get two handles
81487. still can't find in cache
81488. make sure everything will be cached
81489. Low-pri entries will be inserted to head of low-pri pool.
81490. charge
81491. Low-pri entries can take high-pri pool capacity if available
81492. hash
81493. Low-pri entries will be inserted to head of low-pri pool after lookup.
81494. High-pri entries will be inserted to the head of the list after lookup.

81618. SETUP column family "one" -- universal style
81619. Add a column family with no comparator specified
81620. test new iterators
81621. Log file A is not dropped after reopening because default column family's min log number is 0. It flushes to SST file X seqID 2 seqID 3 Current log file is file B now. While flushing, a new log file C is created and is set to current. Both CFs' min log number is set to file C so after flushing file B is deleted. Log file A still remains. Flushed to SST file Y.
81622. VERIFY compaction "one"
81623. **comment:** Speed up threshold = $\min(4 * 2, 4 + (12 - 4)/4) = 6$
label: code-design
81624. Before opening, there are four files: Log file A contains seqID 1 Log file C contains seqID 4, 5 SST file X contains seqID 1 SST file Y contains seqID 2, 3 Min log number: default CF: 0 CF one, two: C When opening the DB, all the seqID should be preserved.
81625. third flush. now, CF [two] should be detected as stale and flushed column family 1 should not be flushed since it's empty flush
81626. namespace rocksdb
81627. flush
81628. Flush the 0th column family to force a roll of the wal log
81629. no tailing
81630. Test that we can retrieve the comparator from a created CF
81631. 100KB
81632. Block flush jobs from running
81633. tailing
81634. Add a column family that doesn't support snapshot
81635. now we sleep again. this is just so we're certain that flush job finished
81636. Note that based on the test setting, this must not be the main thread.
81637. Disable on windows because SyncWAL requires env->IsSyncThreadSafe() to return true which is not so in unbuffered mode.
81638. !ROCKSDB_LITE
81639. GetSortedWalFiles is not supported
81640. setup options. all column families have max_write_buffer_number setup to 10 "default" -> 100KB memtable, start flushing immediately "one" -> 200KB memtable, start flushing with two immutable memtables "two" -> 1MB memtable, start flushing with three immutable memtables "three" -> 90KB memtable, start flushing with four immutable memtables
81641. not a multiple of 4k, round up 4k
81642. [0, (1)] [0, 1, 2]
81643. this test is placed here, because the infrastructure for Column Family test is being used to ensure a roll of wal files. Basic idea is to test that WAL truncation is being detected and not ignored
81644. WAIT for compactions
81645. Create an iterator holding the current super version.
81646. Cuckoo is not supported in lite
81647. Do n memtable flushes, each of which produces an sstable covering the range [small,large].
81648. copy the logs to backup
81649. Before opening, there are two logfiles: Log file A contains seqID 1 Log file D contains seqID 7, 8 Min log number: default CF: D CF one, two: D When opening the DB, log file D should be replayed using the seqID specified in the file.
81650. In this test, we generate enough files to trigger automatic compactions. The automatic compaction waits in NonTrivial:AfterRun We generate more files and then trigger an automatic compaction This will wait because the automatic compaction has files it needs. Once the conflict is hit, the automatic compaction starts and ends Then the manual will run and end.
81651. TRIGGER compaction "one"
81652. first iteration - dont reopen DB before dropping second iteration - reopen DB before dropping
81653. delete old files in backup_logs directory
81654. only 10 files in file cache
81655. assert consistency
81656. This test checks for automatic getting a conflict if there is a manual which has not yet been scheduled. The manual compaction waits in NotScheduled We generate more files and then trigger an automatic compaction This will wait because there is an unscheduled manual compaction. Once the conflict is hit, the manual compaction starts and ends Then another automatic will start and end.
81657. SETUP column family "one" -- level style
81658. this will trigger the flushes
81659. copy the logs from backup back to wal dir
81660. make sure all background compaction jobs can be scheduled
81661. [0]
81662. TEST functions used are not supported
81663. **comment:** ID 3 that was used for dropped column family "three" should not be reused
label: code-design
81664. Speedup threshold = $200 / 4 = 50$
81665. skipped as persisting options is not supported in ROCKSDB_LITE
81666. 3 files for default column families, 1 file for column family [two], zero files for column family [one], because it's empty
81667. anonymous namespace
81668. Flush jobs will close previous WAL files after finishing. By block flush jobs from running, we trigger a condition where the iterator destructor should close the WAL files.
81669. small write buffer size
81670. make sure that all files are deleted when we drop the column family
81671. Add more L0 files and force automatic compaction
81672. Add a column family that supports snapshot. Snapshot stays not supported.
81673. open only a subset of column families
81674. Generate log file A. seqID 1
81675. Log file A is not dropped after reopening because default column family's min log number is 0. It flushes to SST file X seqID 2 seqID 3 Current log file is file B now. While flushing, a new log file C is created and is set to current. Boths' min log number is set to file C in memory, so after flushing file B is deleted. At the

same time, the min log number of default CF is not written to manifest. Log file A still remains. Flushed to SST file Y.
81676. A flush will make `it` hold the last reference of its super version.
81677. recover the DB
81678. Deleting the iterator will clear its super version, triggering closing all files
81679. Allow both of flush and purge job to schedule.
81680. collect wal files
81681. TEST functions in DB are not supported in lite
81682. [0, (1)] [0, 1, (2)] [(2)] [2, 3]
81683. Return the value to associate with the specified key
81684. Start a thread that will drop the first column family and its comparator

81722. create couple files
81723. Make sure we can reopen the DB.
81724. In the meantime flush another file.
81725. c should invoke FullMerge due to kTypeValue at the beginning.
81726. Compaction should output just "a", "e" and "h" keys.
81727. keep skip to "f", aka keep skip to "g+"
81728. keep skip to "z"
81729. Same as ShuttingDownInFilter, but shutdown happens during filter call for a merge operand, not for a value.
81730. If there is a corruption after a single deletion, the corrupted key should be preserved.
81731. Last key the filter was called with.
81732. skip to "d+"
81733. namespace rocksdb
81734. Wait until the filter sees a key >= k and stalls at that key. If `exact`, asserts that the seen key is equal to k.
81735. Expects no merging attempts.
81736. Don't leave tombstones (kTypeDeletion) for filtered keys.
81737. Check that filter was never called again.
81738. b should invoke PartialMergeMulti with two operands.
81739. Unstall filter and wait for SeekToFirst() to return.
81740. Let key 1 through.
81741. See InitIterators() call below for the sequence of keys and their filtering decisions. Here we closely assert that compaction filter is called with the expected keys and only them, and with the right values.
81742. Compaction filter that gets stuck when it sees a particular key, then gets unstuck when told to. Always returns Decition::kRemove.
81743. Check that the compaction iterator did the correct sequence of calls on the underlying iterator.
81744. keep
81745. It is possible that the output of the compaction iterator is empty even if the input is not.
81746. Shutdown during compaction filter call for key 2.
81747. Filter will stall on key >= stall_at. Advance stall_at to unstall.
81748. See InitIterators() call below for why "c" is the only key for which FullMergeV2 should be called.
81749. a should invoke PartialMergeMulti with a single merge operand.

81753. Send these L0 files to L1

81754. Whenever a compaction completes, this listener will try to verify whether the returned CompactionJobStats matches what we expect. The expected CompactionJobStats is added via AddExpectedStats().

81755. 4th Phase: perform L0 -> L1 compaction again, expect higher write amp When subcompactions are enabled, the number of output files increases by 1 because multiple threads are consuming the input and generating output files without coordinating to see if the output could fit into a smaller number of files like it does when it runs sequentially

81756. namespace rocksdb

81757. Insert some deletions for keys that don't exist that are both in and out of the key range

81758. time

81759. Do n memtable compactions, each of which produces an sstable covering the range [small,large].

81760. 3rd Phase: generate sparse L0 files (wider key-range, same num of keys)

81761. Stage 1: Generate several L0 files and then send them to L2 by using CompactRangeOptions and CompactRange(). These files will have a strict subset of the keys from the full key-range

81762. just enough setting to hold off auto-compaction.

81763. namespace

81764. A helper function which verifies whether two CompactionJobStats match. The verification of all compaction stats are done by ASSERT_EQ except for the total input / output bytes, which we use ASSERT_GE and ASSERT_LE with a reasonable bias --- 10% in uncompressed case and 20% when compression is used.

81765. 5th Phase: Do a full compaction, which involves in two sub-compactions. Here we expect to have 1 L0 files and 4 L1 files In the first sub-compaction, we expect L0 compaction.

81766. Here we treat one newly flushed file as an unit. For example, if a newly flushed file is 100k, and a compaction has 4 input units, then this compaction inputs 400k.

81767. 1st Phase: generate "num_L0_files" L0 files.

81768. Destroy it for not alternative WAL dir is used.

81769. Generates the expected CompactionJobStats for each compaction

81770. !ROCKSDB_LITE

81771. !defined(IOS_CROSS_COMPILE)

81772. 2nd Phase: perform L0 -> L1 compaction.

81773. Required if inheriting from testing::WithParamInterface<>

81774. compact two files into one in the last L0 -> L1 compaction

81775. This function behaves with the implicit understanding that two rounds of keys are inserted into the database, as per the behavior of the DeletionStatsTest.

81776. Once a compaction completed, this function will verify the returned CompactionJobInfo with the oldest CompactionJobInfo added earlier in "expected_stats_" which has not yet being used for verification.

81777. Note: key_base must be multiple of num_keys_per_L0_file

81778. Add an expected compaction stats, which will be used to verify the CompactionJobStats returned by the OnCompactionCompleted() callback.

81779. default cfd

81780. Whenever a compaction completes, this listener will try to verify whether the returned CompactionJobStats matches what we expect.

81781. interval needs to be >= 2 so that deletion entries can be inserted that are intended to not result in an actual key deletion by using an offset of 1 from another existing key

81782. Stage 4: Trigger compaction and verify the stats

81783. Return spread of files per level

81784. Verifies whether two CompactionJobStats match.

81785. Add a new record and flush so now there is a L0 file with a value too (not just deletions from the next step)

81786. make sure this is even

81787. Stage 3: Generate L0 files with some deletions so now there are files with the same key range in L0, L1, and L2

81788. An EventListener which helps verify the compaction results in test CompactionJobStatsTest.

81789. filter block index block

81790. Stage 2: Generate files including keys from the entire key range

81791. An EventListener which helps verify the compaction statistics in the test DeletionStatsTest.

81792. file size

81793. disallow trivial move

81794. 1/3 of the data will be updated.

81795. The following statement determines the expected smallest key based on whether it is a full compaction. A full compaction only happens when the number of flushes equals to the number of compaction input runs.

81796. !defined(IOS_CROSS_COMPILE)

81797. namespace rocksdb

81798. **comment:** This test documents the behavior where a corrupt key follows a deletion or a single deletion and the (single) deletion gets removed while the corrupt key gets written out. TODO(noetzli): We probably want a better way to treat corrupt keys.

label: code-design

81799. 81810. returns expected result after compaction

81811. Filters merge operands with value 10.

81812. Test where all operands/merge results are filtered out.

81813. Level 0 files overlap

81814. If no file in L1 being compacted, L0->L1 compaction will be scheduled. being_compacted flag is cleared here.

81815. Tests if the files can be trivially moved in multi level universal compaction when allow_trivial_move option is set In this test as the input files doesn't overlaps, they should be trivially moved.

81816. num_levels - 2 is over target by 1100 + 200

81817. Level 1 size will be 10000 after merging with L0

81818. Universal and FIFO Compactions are not supported in ROCKSDB_LITE

81819. does not own FileMetaData

81820. A compaction should be triggered and pick file 2

81821. file_number
81822. Level 3 score slightly larger than 1
81823. Level 1 is over target by 200
81824. Level 4 exceeds target 1,000,000 by 900 after adding size from level 3 Size ratio L4/L3 is 9.9 After merge from L3, L4 size is 1000900
81825. Level 2 is less than target 10000 even added size of level 1
81826. Level 1 files overlap
81827. ROCKSDB_LITE
81828. num_levels - 3 is over target by 100 + 1000
81829. Tests if the files can be trivially moved in multi level universal compaction when allow_trivial_move option is set In this test as the input files overlaps, they cannot be trivially moved.
81830. Level 1 size will be 1400 after merging with L0
81831. This test exhibits the bug where we don't properly reset parent_index in PickCompaction()
81832. file_size
81833. Chain of overlapping user key ranges (forces ExpandWhileOverlapping() to expand multiple times)
81834. case 3.1: Higher levels (level 3) have overlap
81835. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
81836. case 3.3: Higher levels (level 5) have overlap, but it's only overlapping one key ("d")
81837. Locked file encountered when pulling in extra input-level files with same user keys. Verify we pick the next-best file from the same input level.
81838. output level should be the one above the bottom-most
81839. Locked file encountered when pulling in extra output-level files with same user keys. Expected to skip that compaction and pick the next-best choice.
81840. 6 L0 files, score 3.
81841. Level 2 score 1.8. File 7 is the largest. Should be picked
81842. File not overlapping
81843. Overlapping user keys
81844. Picking file 8 because overlapping ratio is the biggest.
81845. A compaction should be triggered and pick file 2 and 5. and it expands to file 1 and 3 too.
81846. No compaction should be scheduled, if L0 has higher priority than L1 but L0->L1 compaction is blocked by a file in L1 being compacted.
81847. L1 score more than 6.
81848. A compaction should be triggered and pick all files from level 1
81849. Level 3 exceeds target 100,000 of 1000
81850. largest
81851. score(L1) = 3.7 score(L2) = 1.85 There is no eligible file in L1 to compact since both candidates pull in file_number 5U, which overlaps with a file pending compaction (6U). The first eligible compaction is from L2->L3.
81852. Overlapping user keys on same level and output level
81853. Overlaps with file 28, 29, total size 521M
81854. namespace rocksdb
81855. verify whether compaction is needed based on the current size of L0 files.
81856. Merging to the second last level: $(5200 / 2100 + 1) * 1100$ Merging to the last level: $(50000 / 6300 + 1) * 1300$
81857. release the version storage
81858. Pick file 8 because it overlaps with 0 files on level 3.
81859. file 7 and 8 overlap with the same file, but file 8 is smaller so it will be picked. Overlaps with file 26, 27 Overlaps with file 27 Overlaps with file 28, but the file itself is larger. Should be picked.
81860. <- marked for compaction <- this one needs compacting
81861. Level 2 is less than target 10000 even added size of level 1 Size ratio of L2/L1 is 9600 / 1200 = 8
81862. case 3.2: Higher levels (level 5) have overlap
81863. estimated L1->L2 merge: $400 * (9100.0 / 1400.0 + 1.0)$
81864. Set Last level size 50000 num_levels - 1 target 5000 num_levels - 2 is base level with target 1000 (rounded up to max_bytes_for_level_base).
81865. verify the trigger given different number of L0 files.
81866. File 5 has to be included in the compaction
81867. Output level overlaps with the beginning and the end of the chain
81868. Picking file 7 because overlapping ratio is the biggest.
81869. grow the number of inputs in "level" without changing the number of "level+1" files we pick up Expand input level as much as possible no overlapping case
81870. case 1: Higher levels are empty
81871. Level 3 over the target, but since level 4 is empty, we assume it will be a trivial move.
81872. smallest_seq
81873. file_number 2U is largest and thus first choice. But it overlaps with file_number 1U which is being compacted. So instead we pick the next- biggest file, 3U, which is eligible for compaction.
81874. start a brand new version in each test.
81875. smallest
81876. This test checks ExpandWhileOverlapping() by having overlapping user keys ranges (with different sequence numbers) in the input files.
81877. If score in L1 is larger than L0, L1 compaction goes through despite there is pending L0 compaction.
81878. largest_seq
81879. Level 0 files don't overlap
81880. A compaction should be triggered and pick file 2 and 5. It can expand because adding file 1 and 3, the compaction size will exceed mutable_cf_options_.max_bytes_for_level_base.
81881. Level 1 score 1.2
81882. L1 total size 2GB, score 2.2, If one file being compacted, score 1.1.
81883. case 2: Higher levels have no overlap
81884. must return false when there's no files.
81885. input files to compaction process.
81886. **comment:** grow the number of inputs in "level" without changing the number of "level+1" files we pick up Expand input level as much as possible overlapping case
 label: code-design
81887. <- being compacted

81908. Fill levels >= 1

81909. build 2 tables, flush at 5000

81910. if ((i % 100) == 0) fprintf(stderr, "@ %d of %d\n", i, n);

81911. Do it

81912. corrupt an index block of an entire file

81913. namespace rocksdb

81914. corrupt file size

81915. Force compactions by writing lots of values

81916. Write something. If sequence number was not recovered properly, it will be hidden by an earlier write.

81917. Pick file to corrupt

81918. Return the value to associate with the specified key

81919. Pick latest file

81920. WriteBatch tag for first record Somewhere in second block

81921. !ROCKSDB_LITE

81922. very big, we'll trigger flushes manually

81923. make unit test pass for now

81924. Do enough writing to force minor compaction

81925. Do not verify checksums. If we verify checksums then the db itself will raise errors because data is corrupted. Instead, we want the reads to be successful and this test will detect whether the appropriate corruptions have occurred.

81926. The 64 records in the first two log blocks are completely lost.

81927. if one write failed, every subsequent write must fail, too

81928. delete the file

81929. Return the ith key

81930. On Wndows OS Disk cache does not behave properly We do not call FlushBuffers on every Flush. If we do not close the log file prior to the corruption we end up with the first block not corrupted but only the second. However, under the debugger things work just fine but never pass when running normally For that reason people may want to run with unbuffered I/O. That option is not available for WAL though.

81931. Write must eventually fail because of corrupted table

81932. If LRU cache shard bit is smaller than 2 (or -1 which will automatically set it to 0), test SequenceNumberRecovery will fail, likely because of a bug in recovery code. Keep it 4 for now to make the test passes.

81933. Relative to end of file; make it absolute

81934. corrupts exactly one file at level 'level'. if no file found at level, asserts

81935. **comment:** one full file should be readable, since only one was corrupted the other file should be fully non-readable, since index was corrupted
label: code-design

81936. Create a big L0 file and check it compacts into multiple files in L1.

81937. namespace

81938. Write some keys using plain table.

81939. Write some keys using block based table.

81940. Generate one more file in level-0, and should trigger level-0 compaction

81941. namespace rocksdb

81942. Add some values to db.

81943. The following util methods are copied from plain_table_db_test.

81944. 100KB

81945. Write 28 values, each 10016 B ~ 10KB

81946. ROCKSDB_LITE

81947. Add more keys. Delete.

81948. Write 11 values, each 10016 B

81949. Try with empty DB first.

81950. Now add more keys and flush.

81951. Two SST files should be created, each containing 14 keys. Number of buckets will be 16. Total size ~156 KB.

81952. Return spread of files per level

81953. Write some keys using cuckoo table.

81954. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).

81955. disallow trivial move

81956. Duplicate

81957. Update.

81958. Insert same key twice so that they go to different SST files. Then wait for compaction and check if the latest value is stored and old value removed.

81959. Now check keys in read only mode.

81960. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. 81961. Does not exist, and create_if_missing == false: error

81962. Does exist, and error_if_exists == true: error

81963. Add a key

81964. Skip HashCuckooRep as it does not support single delete. FIFO and universal compaction do not apply to the test case. Skip MergePut because single delete does not get removed when it encounters a merge.

81965. **comment:** After a flush, "second", "third" and "fifth" should be removed
label: code-design

81966. CompactedDB

81967. Add more keys

81968. Block flush thread and disable compaction thread

81969. id1 should match id2 because identity was not regenerated

81970. second open should fail

81971. Compaction can still go through even if no thread can flush the mem table.

81972. Add more L0 files

81973. namespace rocksdb

81974. Insert can go through

81975. Full compaction

81976. generate one table with each type of checksum
81977. change when new checksum type added
81978. Unsupported case.
81979. Case 5: snapshot followed by a put followed by another Put Only the last put should remain.
81980. disable compaction
81981. Empty Key Set
81982. this will now also flush the last 2 writes
81983. skip HashCuckooRep as it does not support snapshot
81984. Case1: Delete followed by a put
81985. 10 bytes
81986. after we release the snapshot1, only two values left
81987. verify data with each type of checksum
81988. Fallback to read-only DB
81989. Case 3: Put followed by a delete
81990. This should trigger LogAndApply.
81991. MultiGet
81992. Empty Database, Empty Key Set
81993. Skip HashCuckooRep as it does not support single delete. FIFO and universal compaction do not apply to the test case. Skip MergePut because merges cannot be combined with single deletions.
81994. ROCKSDB_LITE
81995. After the current memtable is flushed, the DEL should have been removed
81996. Write two new keys
81997. Empty Database, Search for Keys
81998. Does not exist, and create_if_missing == true: OK
81999. It is possible to produce empty flushes when using single deletes. Tests whether empty flushes cause issues.
82000. Reopen and flush memtable.
82001. All other combinations are acceptable
82002. after we release the snapshot2, only one value should be left
82003. id1 should NOT match id3 because identity was regenerated
82004. Case 5: Put followed by snapshot followed by another Put Both puts should remain.
82005. four kv pairs * two bytes per value
82006. We have only one valid snapshot snapshot2. Since snapshot1 is not valid anymore, "first" should be removed by a compaction.
82007. 'foo' should be there because its put has WAL enabled.
82008. All entries (including duplicates) exist before any compaction or flush is triggered.
82009. Case 4: Put followed by another Put
82010. Try with both a short key and a long key
82011. Flush can still go through.
82012. **comment:** On Windows you can have either memory mapped file or a file with unbuffered access. So this asserts and does not make sense to run

82060. Make sure filter block is in cache.

82061. flush all data from memtable so that reads are from block cache

82062. read and cache data block

82063. Clear strict capacity limit flag. This time we shall hit compressed block cache.

82064. namespace rocksdb

82065. options.compression = kNoCompression;

82066. Release iterators and access cache again.

82067. compressed doesn't have any hits since blocks are not compressed on storage

82068. anonymous namespace

82069. adding data block

82070. cache evicted old index and block entries

82071. both block cache and compressed cache, but DB is not compressed also, make block cache sizes bigger, to trigger block cache hits

82072. high compression ratio

82073. set the cache capacity to the current usage

82074. index/filter blocks added to block cache right after table creation.

82075. A mock cache wraps LRU Cache, and record how many entries have been inserted for each priority.

82076. Make sure index block is in cache.

82077. Set a small enough block size so that each key-value get its own block.

82078. check that we triggered the appropriate code paths in the cache

82079. Load blocks into cache.

82080. SNAPPY

82081. Write 8MB (80 values, each 100K)

82082. Miss count should remain the same.

82083. ROCKSDB_LITE

82084. no block cache, only compressed cache

82085. Totally 3 files created up to now

82086. Make sure that when options.block_cache is set, after a new table is created its index/filter blocks are added to block cache.

82087. Data block should be inserted with low priority.

82088. Run this test three iterations. Iteration 1: only a uncompressed block cache Iteration 2: only a compressed block cache Iteration 3: both block cache and compressed cache Iteration 4: both block cache and compressed cache, but DB is not compressed

82089. default column family doesn't have block cache

82090. After disabling options.paranoid_file_checks. NO further block is added after generating a new file.

82091. Create a new SST file. This will further trigger a compaction and generate another file.

82092. Access data block.

82093. both compressed and uncompressed block cache

82094. Compressed block cache cannot be pinned.

82095. 200 bytes are enough to hold the first two blocks

82096. only uncompressed block cache

82097. only index/filter were added

82098. Test with strict capacity limit.

82099. Create a new table.

82100. Create a new table

82101. Set strict capacity limit flag. Now block will only load into compressed block cache.

82102. DB tests related to bloom filter.

82103. Full Filter Block

82104. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. See the AUTHORS file for names of contributors.

82105. 11 RAND I/Os

82106. Restart with only prefix bloom is allowed.

82107. Lookup present keys. Should rarely read from either sstable.

82108. Now that we know the filter blocks exist in the last level files, see if filter caching is skipped for this optimization

82109. Needs insert some keys to make sure files are not filtered out by key ranges.

82110. Reopen with the same setting: only whole key is used

82111. sanity checks

82112. GROUP 1

82113. Try to create a DB with mixed files:

82114. In this case needs insert some keys to make sure files are not filtered out by key ranges.

82115. Generate randomly shuffled keys, so the updates are almost random.

82116. Check filter block ignored for files preloaded during DB::Open()

82117. namespace rocksdb

82118. public testing::WithParamInterface<bool> {

82119. ChangeCompactOptions() only changes compaction style, which does not trigger reset of table_factory

82120. **comment:** Lookup present keys. Should rarely read from small sstable.
label: code-design

82121. Part 2 (read path): rewrite last level with blooms, then verify they get cached only if !optimize_filters_for_hits

82122. Write DB with only full key filtering.

82123. Create with full filter

82124. In the current implementation partitioned filters depend on partitioned indexes

82125. **comment:** KeyMayExist function only checks data in block caches, which is not used by plain table format.
label: code-design

82126. Check db with partitioned full filter

82127. index and data block

82128. prefix will be x????

82129. Block Filter Block

82130. GROUP 0

82131. GROUP 2

82132. Reopen with both of whole key off and prefix extractor enabled. Still no bloom filter should be used.

82133. namespace

82134. Now we have two files: File 1: An older file with prefix bloom. File 2: A newer file with whole bloom filter.

82135. move to level 1

82136. Restart with both filters are allowed

82137. With partitioned filter we read one extra filter per level per each missed read.

82138. Populate multiple layers

82139. 1 Insert 2 K-V pairs into DB 2 Call Get() for both keys - expect memtable bloom hit stat to be 2 3 Call Get() for nonexistent key - expect memtable bloom miss stat to be 1 4 Call Flush() to create SST 5 Call Get() for both keys - expect SST bloom hit stat to be 2 6 Call Get() for nonexistent key - expect SST bloom miss stat to be 1 Test both: block and plain SST

82140. not supported in plain table

82141. end of while

82142. Check SST bloom stats

82143. assert that no new files were opened and no new blocks were read into block cache.

82144. Was not added to filter but rocksdb will try to read it from the filter

82145. Required if inheriting from testing::WithParamInterface<>

82146. Same scenario as in BloomStatsTest but using an iterator

82147. ROCKSDB_LITE

82148. File 1 will has it filtered out. File 2 will not, as prefix `foo` exists in the file.

82149. Check db with block_based filter

82150. Reopen with whole key filtering enabled and prefix extractor NULL. Bloom filter should be off for both of whole key and prefix bloom.

82151. Without block cache, we read an extra partition filter per each level*read and a partition index per each read

82152. A wrapped bloom over default FilterPolicy

82153. not in DB

82154. Check db with full filter

82155. setting > -1 makes it not preload all files

82156. Check if filter is useful

82157. **comment:** KeyMayExist can lead to a few false positives, but not false negatives. To make test deterministic, use a much larger number of bits per key-20 than bits in the key, so that false positives are eliminated
label: code-design

82158. Create with block based filter

82159. Add a large key to make the file contain wide range

82160. Check filter block ignored for file trivially-moved to bottom level

82161. No Level 0 file. Create one.

82162. Try to create a DB with mixed files.

82163. check memtable bloom stats

82164. Check filter block not cached for iterator

82165. Seek to key that was not in Domain

82166. Not in domain, wont be added to filter

82167. check SST bloom stats

82168. Check if they can be found

82169. column family index

82170. disallow trivial move

82171. Generate 11 sst files with the following prefix ranges. GROUP 0: [0,10] (level 1) GROUP 1: [1,2], [2,3], [3,4], [4,5], [5, 6] (level 0) GROUP 2: [0,6], [0,7], [0,8], [0,9], [0,10] (level 0) A seek with the previous API would do 11 random I/Os (to all the files). With the new API and a prefix filter enabled, we should only do 2 random I/O, to the 2 files containing the key.

82172. db configs

82173. Prevent auto compactions triggered by seeks

82174. Now we have three sorted run, L0, L5 and L6 with most files in L6 have no bloom filter. Most keys be checked bloom filters twice.

82175. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). See the AUTHORS file for names of contributors.

82176. overwrite all the 100K keys once again.

82177. All the files are in the lowest level. Verify that all but the 100001st record has sequence number zero. The 100001st record is at the tip of this snapshot and cannot be zeroed out.

82178. Put some data.

82179. create a new database with the compaction filter in such a way that it deletes all keys

82180. Compaction filters should only be applied to records that are newer than the latest snapshot. However, if the compaction filter asks to ignore snapshots records newer than the snapshot will also be processed

82181. namespace rocksdb

82182. empty db

82183. push all files to the highest level L2. This means that all keys should pass at least once via the compaction filter

82184. write all the keys once again.

82185. push all files to lower levels

82186. Number of skips in tables: 2, 3, 3, 3.

82187. this will produce empty file (delete compaction filter)

82188. Make sure next file is much smaller so automatic compaction will not be triggered.

82189. Filter out keys with value is 2.

82190. Scan the entire database to ensure that nothing is left

82191. Compaction filter never applies to merge keys.

82192. The filter should delete 10 records.

82193. Write 100K+1 keys, these are written to a few files in L0. We do this so that the current snapshot points to the 100001 key. The compaction filter is not invoked on keys that are visible via a snapshot because we anyways cannot delete it.

82194. put some data

82195. Delete Filter Factory which ignores snapshots

82196. verify that all keys now have the new value that was set by the compaction process.

82197. The filter should delete 40 records.

82198. The sequence number of the remaining record is not zeroed out even though it is at the level Lmax because this record is at the tip

82199. In the same compaction, both of value type and merge type keys need to be deleted based on compaction filter, and there is a merge type for the key. For both keys, compaction filter results are ignored.

82200. ROCKSDB_LITE

82201. Scan the entire database as of the snapshot to ensure that nothing is left

82202. We have deleted 10 keys from 40 using the compaction filter Keys 6-9 before the snapshot and 100-105 after the snapshot

82203. This is a static filter used for filtering kvs during the compaction process.

82204. Key ranges in tables are [0, 38], [106, 149], [212, 260], [318, 371].

82205. re-write all data again

82206. Push all files to the highest level L2. Verify that the compaction is each level invokes the filter for all the keys in that level.

82207. In the same compaction, a value type needs to be deleted based on compaction filter, and there is a merge type for the key. compaction filter result is ignored.

82208. Force a manual compaction

82209. value key can be deleted based on compaction filter, leaving only merge keys.

82210. Write 100K keys, these are written to a few files in L0.

82211. Write several keys.

82212. Compaction filters should only be applied to records that are newer than the latest snapshot. This test inserts records and applies a delete filter.

82213. Skip x if floor(x/10) is even, use range skips. Requires that keys are zero-padded to length 10.

82214. Push all files to the highest level L2. This triggers the compaction filter to delete all keys, verify that at the end of the compaction process, nothing is left.

82215. snapshots
82216. push all files to lower levels. This should invoke the compaction filter for all 100000 keys.
82217. Verify total number of keys is correct after manual compaction.
82218. Release the snapshot and compact again -> now all records should be removed.
82219. Tests the edge case where compaction does not produce any output -- all entries are deleted. The compaction should create bunch of 'DeleteFile' entries in VersionEdit, but none of the 'AddFile's.
82220. skipped
82221. must have much smaller db size.
82222. filter out cases for table properties queries.
82223. Wait for compaction to finish
82224. Second non-trivial compaction is triggered
82225. **comment:** Create two more files for one column family, which triggers speed up condition, three compactions will be scheduled.
 label: code-design
82226. Since data is non-overlapping we expect compaction to initiate a trivial move
82227. 500KB
82228. 8 MB
82229. Verify all L0 files are still there.
82230. Multiple files in L0 No files in L1
82231. 2 files in L2
82232. b.smallestkey <= a.smallestkey <= b.largestkey
82233. If update stats on DB::Open is disable, we don't expect deletion entries taking effect.
82234. level1_file.name
82235. (1, 4, 1)
82236. Eventually the cancelled compaction will be rescheduled and executed.
82237. This test triggers move compaction and verifies that the file is not deleted when it's part of move compaction
82238. github issue #2249
82239. Another 110KB triggers a compaction to 400K file to fill up first path
82240. iter 1 -- delete_obsolete_files_period_micros == 0
82241. Create 1MB sst file
82242. block compactions
82243. Add 2 non-overlapping files
82244. Delete keys in range [1, 4]. These L0 files will be compacted with L1: - Tombstones for keys 2 and 4 can be dropped early. - Tombstones for keys 1 and 3 must be kept due to L2 files' key-ranges.
82245. Stage 1: generate a db with level compaction
82246. Reopen the DB with stats-update disabled
82247. level1_files
82248. file 5 [400 => 500)
82249. make sure all key-values are still there.
82250. stop the compaction thread until we simulate the file creation failure.
82251. Stage 2: reopen with universal compaction - should fail
82252. Trivial move the two non-overlapping files to level 6
82253. L0 file meta
82254. this range overlap with the next one
82255. One for compaction input, one for verifying compaction results.
82256. compaction options
82257. Compact all
82258. regression test for issue #2722: L0->L0 compaction can resurrect deleted keys from older L0 files if L1+ files' key-ranges do not include the key.
82259. Compaction will do L0=>L1 L1=>L2 L2=>L3 (3 trivial moves)
82260. Same ranges as above but overlapping
82261. Create new iterator for: (1) 1 for verifying flush results (2) 3 for compaction input files (3) 1 for verifying compaction results.
82262. First three 110KB files are not going to second path. After that, (100K, 200K)
82263. disallow trivial move
82264. File moved From L0 to L1 0 files in L0 1 file in L1
82265. Push data from level 0 to level 1 to force all data to be deleted Note that we don't delete level 0 files
82266. release snap so that first instance of key(3) can have seqId=0
82267. File with keys [100 => 199]
82268. Trigger a long memtable compaction and reopen the database during it Goes to 1st log file Fills memtable Triggers compaction Goes to new log file
82269. Compact just the new range
82270. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. 82271. create two files in l1 that we can compact
82272. index: 0 1 2 3 4 5 6 7 8 9 size: 1MB 1MB 1MB 1MB 1MB 2MB 1MB 1MB 1MB 1MB score: 1.5 1.3 1.5 2.0 inf Files 0-4 will be included in an L0->L1 compaction. L0->L0 will be triggered since the sync points guarantee compaction to base level is still blocked when files 5-9 trigger another compaction. Files 6-9 are the longest span of available files for which work-per-deleted-file decreases (see "score" row above).
82273. note CompactionOptions::output_file_size_limit is unset.
82274. trigger compaction when we have 2 files
82275. this time we're expecting significant drop in size.
82276. round 3 --- reopen db with auto_compaction on and see if deletion compensation still work.
82277. 1 files in L0
82278. Make sure the number of L0 files can trigger compaction.
82279. Only 1 file in L0
82280. this file should have been compacted away
82281. each value is 10K
82282. The auto compaction is scheduled but waited until here
82283. make l0 files' ranges overlap to avoid trivial move
82284. 10 KB
82285. (1, 4, 4)
82286. key 0 serves both to prevent trivial move and as the key we want to verify is not resurrected by L0->L0 compaction.
82287. the following only disable stats update in DB::Open() and should not affect the result of this test.
82288. Otherwise, we should see a significant drop in db size.
82289. file 3 [0 => 200]
82290. a.smallestkey < b.smallestkey <= a.largestkey
82291. **comment:** Disable as the test is flaky.
 label: test
82292. Verify number of compactions allowed will come back to 1.
82293. Expect compaction to fail here as one file will fail its creation.
82294. (1, 4, 7)

82295. 2 files in L2, 1 in L1
82296. fill up the DB
82297. Compaction will do L0=>L1 L1=>L2 L2=>L3 (3 trivial moves) then compacte the bottommost level L3=>L3 (non trivial move)
82298. 1 MB
82299. lookup iterator from table cache and no need to create a new one.
82300. Compaction will do L0=>L1 (trivial move) then move L1 files to L3
82301. Unblock all threads to unblock all compactions.
82302. move both files down to l1
82303. SYNC_POINT is not supported in released Windows mode.
82304. File with keys [0 => 99]
82305. this should execute L1->L2 (move)
82306. 110KB
82307. Create two 1MB sst files
82308. First non-trivial compaction is triggered
82309. Check level compaction with compact files
82310. Verify again after reopen.
82311. We expect that all the files were trivially moved from L0 to L1
82312. at least L0 and L1 L0 has the 2MB file (not compacted) and 4MB file (output of L0->L0)
82313. Preloading iterator issues one table cache lookup and creates a new table reader. One file is created for flush and one for compaction. Compaction inputs make no table cache look-up for data/range deletion iterators
82314. Create several column families. Make compaction triggers in all of them and see number of compactions scheduled to be less than allowed.
82315. trigger L0 compaction
82316. Verify level sizes
82317. Infinitely large
82318. second non-trivial compaction
82319. **comment:** Now all column families qualify compaction but only one should be scheduled, because no column family hits speed up condition.
 label: code-design
82320. Delete archival files.
82321. **comment:** Currently, the test relies on the number of calls to InputCompressionMatchesOutput() per compaction.
 label: code-design
82322. **comment:** This tests for a bug that could cause two level0 compactions running concurrently TODO(aekmekji): Make sure that the reason this fails when run with max_subcompactions > 1 is not a correctness issue but just inherent to running parallel L0-L1 compactions
 label: code-design
82323. index: 0 1 2 3 4 5 6 7 8 9 size: 1MB score: 1.25 1.33 1.5 2.0 inf Files 0-4 will be included in an L0->L1 compaction. L0->L0 will be triggered since the sync points guarantee compaction to base level is still blocked when files 5-9 trigger another compaction. All files 5-9 are included in the L0->L0 due to work-per-deleted file decreasing. Put a key-value in files 0-4. Delete that key in files 5-9. Verify the L0->L0 preserves the deletion such that the key remains deleted.
82324. this should execute both L0->L1 and L1->L2 (merge with previous file)
82325. round 1 --- insert key/value pairs.
82326. file 4 [300 => 400)
82327. All the TEST_P tests run once with sub_compactions disabled (i.e. options.max_subcompactions = 1) and once with it enabled
82328. (1, 4, 3)
82329. create first file and flush to l0
82330. nowait
82331. create second file and flush to l0
82332. file 2 [100 => 300]
82333. iterator is holding the file
82334. create 3 files in l0 so to trigger compaction
82335. Only verifying compaction outputs issues one table cache lookup for both data block and range deletion block).
82336. !defined(ROCKSDB_LITE) namespace rocksdb
82337. at least L0 and L1 L0 has a single output file from L0->L0
82338. Compaction range falls after files
82339. put key 1 and 3 in separate L1, L2 files. So key 0, 2, and 4+ fall outside these levels' key-ranges.
82340. Compaction will initiate a trivial move from L0 to L1
82341. (1, 4, 6)
82342. 2 files in L2, 1 in L0
82343. Reopening moves updates to level-0
82344. Compaction will do L0=>L1 L1=>L2 L2=>L3 (3 trivial moves) and will skip bottommost level compaction
82345. Fail the first file creation.
82346. third pass with universal compaction
82347. non overlapping ranges
82348. let compactions go
82349. Identifies all files between level "min_level" and "max_level" which has overlapping key range with "input_file_meta".
82350. (1, 4, 2)
82351. All key-values must exist after compaction fails.
82352. Since we do a normal stats update on db-open, there will be more random open files.
82353. As stats-update is disabled, we expect a very low number of random file open. Note that this number must be changed accordingly if we change the number of files needed to be opened in the DB::Open process.
82354. level1_file.size
82355. Many files 4 [300 => 4300)
82356. prevents trivial move
82357. file 1 [0 => 300]
82358. The auto compaction will wait until the manual compaction is registered before processing so that it will be cancelled.
82359. second pass with universal compaction
82360. file 1 [0 => 100]
82361. Large write buffer
82362. put extra key to trigger flush
82363. Make sure RocksDB will not get into corrupted state.
82364. First three 110KB files are going to level 0 After that, (100K, 200K)
82365. Verify manual compaction doesn't fill block cache
82366. This test verify UpdateAccumulatedStats is not on if options.skip_stats_update_on_db_open = true The test will need to be updated if the internal behavior changes.
82367. make sure all background compaction jobs can be scheduled
82368. Compaction range falls before files
82369. Stage 4: re-open in universal compaction style and do some db operations
82370. Another 110KB triggers a compaction to 400K file to fill up level 0
82371. Populate a different range
82372. Write 100KB (100 values, each 1K)

82373. Check that writes done during a memtable compaction are recovered if the database is shutdown during the memtable compaction.
82374. Create two more 1MB sst files
82375. options = CurrentOptions(options);
82376. Block all threads in thread pool.
82377. Verify L0 -> L1 compaction does fail.
82378. Repeat the reopen process, but this time we enable stats-update.
82379. insert relatively small amount of data to trigger auto compaction.
82380. 2 files in L6, 1 file in L5
82381. Make sure all overlapping files do not exist after compaction
82382. **comment:** Should speed up compaction when there are 4 files.
 label: code-design
82383. 2 files in L6
82384. 2 files in L0
82385. anonymous namespace
82386. 200KB
82387. b.smallestkey <= a.largestkey <= b.largestkey
82388. round 2 --- disable auto-compactions and issue deletions.
82389. Before two non-trivial compactions are installed, there are 3 files in L0
82390. (1, 4)
82391. file 2 [600 => 700]
82392. Purpose of dependencies: 4 -> 1: ensure the order of two non-trivial compactions 5 -> 2 and 5 -> 3: ensure we do a check before two non-trivial compactions are installed
82393. **comment:** First two levels have no compression, so that a trivial move between them will be allowed. Level 2 has Zlib compression so that a trivial move to level 3 will not be allowed
 label: code-design
82394. file 6 [500 => 600)

82673. Verify if DB can be reopen after setting options.
82674. RocksDB lite don't support dynamic options.
82675. test with level0_stop_writes_trigger
82676. ROCKSDB_LITE
82677. Background compaction executed.
82678. Need to insert two keys to avoid trivial move.
82679. default value
82680. examine the table cache (actual size should be 1014)
82681. Wait for stall condition recalculate.

82682. Block background compaction.
82683. GetOptions should be able to get latest option changed by SetOptions.
82684. Verify that candidate files set is empty when no full scan requested.
82685. namespace rocksdb
82686. Phase 1. Simply issue Put() and expect "cur-size-all-mem-tables" equals to "size-all-mem-tables"
82687. small write buffer
82688. compression ratio is -1.0 when no open files at level
82689. Restart the DB. Although number of files didn't reach options.level0_file_num_compaction_trigger, compaction should still be triggered because of the need-compaction hint.
82690. After reopening, no table reader is loaded, so no memory for table readers
82691. "192" is the size of the metadata of two empty skiplists, this would break if we change the default skiplist implementation
82692. Trigger automatic compactions.
82693. Small write buffer
82694. This ensures there no compaction happening when we call GetProperty().
82695. Clear internal stats
82696. Trigger compaction
82697. Block sync calls
82698. In the second round, add iterators.
82699. Come back to write to default column family
82700. Close before mock_env destructs.
82701. Set sizes to both background thread pool to be 1 and block them.
82702. ROCKSDB_LITE namespace rocksdb
82703. Verify the same set of properties through GetIntProperty
82704. anonymous namespace
82705. Reopen and issue iterating. See thee latency tracked
82706. Fill memtable
82707. Put common data ("key") at end to prevent delta encoding from compressing the key effectively
82708. no compression at L0, so ratio is less than one
82709. **comment:** TODO(techdept) : Disabled flaky test #12863555
 label: test
82710. Reopen and issue Get(). See thee latency tracked
82711. Phase 5. Reopen, and expect all these three counters to be the same again.
82712. **comment:** TODO(noetzli) kFlushesPerRound does not really correlate with how many flushes happen.
 label: code-design
82713. Use an iterator to hold current version
82714. Test rocksdb.num-live-versions
82715. **comment:** Data at L1 should be highly compressed thanks to Snappy and redundant data in values (ratio is 12.846 as of 4/19/2016).
 label: code-design
82716. Make sure that there is no flush between getting the two properties.
82717. **comment:** Issue flush and expect larger memory usage of table readers.
 label: code-design
82718. Phase 3. Delete iterators and expect "size-all-mem-tables" shrinks whenever we release an iterator.
82719. Gives larger bias here as index block size, filter block size, and data block size become much harder to estimate in this test.
82720. Expect all these three counters to be the same.
82721. ROCKSDB_LITE
82722. "rocksdb.estimate-oldest-key-time" only available to fifo compaction.
82723. default CF Create 4 tables in default column family
82724. Phase 0. The verify the initial value of all these properties are the same as we have no mem-tables.
82725. After reading a key, at least one table reader is loaded.
82726. CF 1 should show no histogram.
82727. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). See the AUTHORS file for names of contributors.
82728. If C++ gets a std::string_literal, this would be better to check at compile-time using static_assert.
82729. We iterate every key twice. Is it a bug?
82730. Expect the size shrinking
82731. put something and read it back , CF 1 should show histogram.
82732. Force flush to prevent flush from happening between getting the properties or after getting the properties and before the new round.
82733. Phase 2. Keep issuing Put() but also create new iterators. This time we expect "size-all-mem-tables" > "cur-size-all-mem-tables".
82734. Get() after flushes, See latency histogram tracked.
82735. Create 4 tables
82736. Wait for compaction to be done. This is important because otherwise RocksDB might schedule a compaction when reopening the database, failing assertion (A) as a result.
82737. Create 2 files
82738. Release sync calls
82739. Make them never flush
82740. When "max_open_files" is -1, we read all the files for "rocksdb.estimate-num-keys" computation, which is the ground truth. Otherwise, we sample 20 newest files to make an estimation. Formula: lastest_20_files_active_key_ratio * total_files
82741. in no iterator case, these two number should be the same.
82742. (A)
82743. Clear Level 0 so that when later flush a file with deletions, we don't trigger an organic compaction.
82744. options.max_open_files preloads table readers.
82745. Write 100KB (100 values, each 1K)
82746. When i == 1, compaction will output some files to L1, at which point L1 is not bottommost so range deletions cannot be compacted away. The new L1 files must be generated with non-overlapping key ranges even though multiple subcompactions see the same ranges deleted, else an assertion will fail. Only enable auto-compactions when we're ready; otherwise, the oversized L0 (relative to base_level) causes the compaction to run earlier.
82747. Write 1MB (256 values, each 4K)
82748. Regression test for bug where sentinel range deletions (i.e., ones with sequence number of zero) were included in output files. snapshot protects range tombstone from dropping due to becoming obsolete.
82749. input_level
82750. During compaction to bottommost level, verify range tombstones older than the oldest snapshot are removed, while others are preserved.
82751. we need to prevent trivial move using Puts so compaction will actually process the merge operands.
82752. Make sure a given key appears in each file so compaction won't be able to use trivial move, which would happen if the ranges were non-overlapping. Also, we need an extra element since flush is only triggered when the number of keys is one greater than SpecialSkipListFactory's limit. We choose a key outside the key-range used by the test to avoid conflict.
82753. put enough keys to fill up the first subcompaction, and later range-delete them so that the first subcompaction outputs no key-values. In that case it'll consider making an SST file dedicated to range deletions.
82754. background compaction may happen early for kFilesPerLevel'th file

82755. Delete merge operands from all but the last file
82756. Write half of the keys before the tombstone and half after the tombstone. Only covered keys (i.e., within the range and older than the tombstone) should be deleted.
82757. give files overlapping key-ranges to prevent trivial move
82758. This puts table caches in the state of being externally referenced only so they are destroyed immediately upon iterator unreferencing.
82759. regression test for exactly filled compaction output files. Previously another file would be generated containing all range deletions, which could invalidate the non-overlapping file boundary invariant.
82760. Want max_compaction_bytes to trigger the end of compaction output file, not target_file_size_base, so make the latter much bigger
82761. disallow_trivial_move
82762. range tombstone covers first half of the previous file
82763. 0+1+2+...+9
82764. PlainTableFactory and NumTableFilesAtLevel() are not supported in ROCKSDB_LITE
82765. namespace rocksdb
82766. output_level
82767. snapshot prevents key from being deleted during flush
82768. Now L1-L3 are full, when we compact L1->L2 we should see (1) subcompactions happen since input level > 0; (2) range deletions are not dropped since output level is not bottommost. If no file boundary assertion fails, that probably means universal compaction + subcompaction + range deletion are compatible.
82769. the above range tombstone can be dropped, so that one alone won't cause a dedicated file to be opened. We can make one protected by snapshot that must be considered. Make its range outside the first subcompaction's range to exercise the tricky part of the code.
82770. delete [95,105) in two files, [295,305) in next two
82771. end
82772. Regression test for #2752. Range delete tombstones between different snapshot stripes are not stored in order, so the first tombstone of each snapshot stripe should be checked as a smallest candidate.
82773. The RangeDelAggregator holds pointers into range deletion blocks created by table readers. This test ensures the aggregator can still access those blocks even if it outlives the table readers that created them. DBIter always keeps readers open for L0 files. So, in order to test aggregator outliving reader, we need to have deletions in L1 files, which are opened/closed on-demand during the scan. This is accomplished by setting kNumRanges > level0_stop_writes_trigger, which prevents deletions from all lingering in L0 (there is at most one range deletion per L0 file). The first L1 file will contain a range deletion since its begin key is 0. SeekToFirst() references that table's reader and adds its range tombstone to the aggregator. Upon advancing beyond that table's key-range via Next(), the table reader will be unreferenced by the iterator. Since we manually call Evict() on all readers before the full scan, this unreference causes the reader's refcount to drop to zero and thus be destroyed. When it is destroyed, we do not remove its range deletions from the aggregator. So, subsequent calls to Next() must be able to use these deletions to decide whether a key is covered. This will work as long as the aggregator properly references the range deletion block.
82774. 6+7+8+9
82775. make sure compaction treats files containing a split range deletion in the input level as an atomic unit. I.e., compacting any input-level file(s) containing a portion of the range deletion causes all other input-level files containing portions of that same range deletion to be included in the compaction.
82776. Ensures range deletion spanning multiple compaction output files that are cut by max_compaction_bytes will have non-overlapping key-ranges.
<https://github.com/facebook/rocksdb/issues/1778>
82777. 6+7+8+9 (earlier operands covered by tombstone)
82778. snapshot protects range tombstone from dropping due to becoming obsolete.
82779. insert range deletions [95,105) in two files, [295,305) in next two to prepare L1 for later manual compaction.
82780. Must be > 1 so the first L1 file can be closed before scan finishes
82781. exclusive
82782. 1+2+...+9
82783. first iteration verifies query correctness in memtable, second verifies query correctness for a single SST file
82784. background compaction may happen early for kNumFiles'th file
82785. num_entries_flush
82786. ROCKSDB_LITE
82787. each block holds two keys
82788. For L1+, iterators over files are created on-demand, so need seek
82789. !ROCKSDB_UBSAN_RUN
82790. put extra key to trigger final flush
82791. It spans the whole key-range, thus will be included in all output files
82792. Hold a snapshot to separate these two delete ranges.
82793. i == 0: CompactFiles i == 1: CompactRange i == 2: automatic compaction
82794. Write 12K (4 values, each 3K)
82795. iterations check unsupported in memtable, l0, and then l1
82796. prevents empty after compaction
82797. deletes [0, 5]
82798. obsolete after compaction
82799. gaps between ranges creates sentinels in our internal representation
82800. regression test for #2743. the range delete tombstones in memtable should be added even when Get() skips searching due to its prefix bloom filter 1MB 8KB
82801. Write a third before snapshot, a third between snapshot and tombstone, and a third after the tombstone. Keys older than snapshot or newer than the tombstone should be preserved.
82802. need a L1 file for subcompaction to be triggered
82803. put extra key to trigger flush
82804. Hold a snapshot so range deletions can't become obsolete during compaction to bottommost level (i.e., L1).
82805. SpecialSkipListFactory lets us specify maximum number of elements the memtable can hold. It switches the active memtable to immutable (flush is prevented by the above options) upon inserting an element that would overflow the memtable.
82806. Copyright (c) 2016-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
82807. begin
82808. NumTableFilesAtLevel() is not supported in ROCKSDB_LITE
82809. protected by snapshot
82810. output_path_id
82811. Iterates kNumFiles * kNumPerFile + 1 times since flushing the last file requires an extra entry.
82812. Keep clearing block cache's LRU so range deletion block can be freed as soon as its refcount drops to zero.
82813. Put a snapshot before the range tombstone, verify an iterator using that snapshot sees all inserted keys.
82814. extra entry to trigger SpecialSkipListFactory's flush
82815. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. 82816. If pending output guard does not work correctly, PurgeObsoleteFiles() will delete the file that Compaction is trying to create, causing this: error db/db_test.cc:975: IO error: /tmp/rocksdbtest-1552237650/db_test/000009.sst: No such file or directory
82817. Randomly sleep shortly
82818. This flush will cause bg_error_ and will fail
82819. used in the main loop assert
82820. Live SST files = 0 Total SST files = 0
82821. Compaction will do trivial move from L0 to L1
82822. Close DB and destroy it using DeleteScheduler
82823. Verify the total files size

82824. Hold BackgroundEmptyTrash
82825. Live SST files = 0 Total SST files = 5 (used in 2 version)
82826. clear error to ensure compaction callback is called
82827. Compaction will delete files from L0 in first db path and generate a new file in L1 in second db path
82828. trigger compaction when we have 2 files
82829. If the moved file is actually deleted (the move-safeguard in ~Version::Version() is not there), we get this failure: Corruption: Can't access /000009.sst
82830. namespace rocksdb
82831. 1 Create some SST files by inserting K-V pairs into DB 2 Close DB and change suffix from ".sst" to ".ldb" for every other SST file 3 Open DB and check if all key can be read
82832. **comment:** File just flushed is too big for L0 and L1 so gets moved to L2.
label: code-design
82833. Create a DB with 2 db_paths, and generate multiple files in the 2 db_paths using CompactRangeOptions, make sure that files that were deleted from first db_path were deleted using DeleteScheduler and files in the second path were not.
82834. This file should have been deleted during last compaction
82835. We have deleted the 4 sst files in the delete_scheduler
82836. this should execute both L0->L1 and L1->(move)->L2 compactions
82837. Generate 5 files in L0
82838. This test triggers move compaction and verifies that the file is not deleted when it's part of move compaction
82839. finish the flush!
82840. Live SST files = 5 Total SST files = 5
82841. No files were moved
82842. Open DB with infinite max open files - First iteration use 1 thread to open files - Second iteration use 5 threads to open files
82843. 2 MB 1 MB
82844. Compaction will move the 4 files in L0 to trash and create 1 L1 file
82845. Close db before mock_env destruct.
82846. Set wait until time to before current to force not to sleep.
82847. Generate a file containing 100 keys.
82848. Check the estimated db size vs the db limit just to make sure we dont run into an infinite loop ~60 bytes per key
82849. Verify that we are tracking all sst files in dbname_
82850. Reopening the DB will load all existing files
82851. low limit for size calculated using sst files
82852. 1 MB
82853. Turn timed wait into a simulated sleep
82854. hold current version
82855. Live SST files = 1 (compacted file) Total SST files = 6 (5 original files + compacted file)
82856. Delete all keys and compact, this will delete all live files
82857. block the flush
82858. Compact 5 files into 1 file in L0
82859. Live SST files = 0 Total SST files = 1 (compacted file)
82860. ROCKSDB_LITE
82861. Set the maximum allowed space usage to the current total size
82862. This reproduces a bug where we don't delete a file because when it was supposed to be deleted, it was blocked by pending_outputs Consider: 1. current file_number is 13 2. compaction (1) starts, blocks deletion of all files starting with 13 (pending outputs) 3. file 13 is created by compaction (2) 4. file 13 is consumed by compaction (3) and file 15 was created. Since file 13 has no references, it is put into VersionSet::obsolete_files_ 5. FindObsoleteFiles() gets file 13 from VersionSet::obsolete_files_. File 13 is deleted from obsolete_files_set. 6. PurgeObsoleteFiles() tries to delete file 13, but this file is blocked by pending outputs since compaction (1) is still running. It is not deleted and it is not present in obsolete_files_ anymore. Therefore, we never delete it.
82863. Create 4 files in L0
82864. **comment:** We don't propagate oldest-key-time table property on compaction and just write 0 as default value. This affect the exact table size, since we encode table properties as varint64. Force time to be 0 to work around it. Should remove the workaround after we propagate the property on compaction.
label: code-design
82865. Live SST files = 0 Total SST files = 6 (5 original files + compacted file)
82866. Every time we write to a table file, call FOF/POF with full DB scan. This will make sure our pending_outputs_ protection work correctly
82867. 110KB
82868. Verify that we track all the files again after the DB is closed and opened
82869. Create two 1MB sst files
82870. 512 Kb
82871. Insert 2.5MB data, which should trigger a flush because we exceed write_buffer_size. The flush will be blocked with block_first_time pending_file is protecting all the files created after
82872. Create 12 Files in L0 (then move then to L2)
82873. Create 12 files in L0
82874. 1 Mb / Sec
82875. force
82876. Live SST files = 5 Total SST files = 5 (used in 2 version)
82877. 10 Kbs / Sec
82878. We created 4 sst files in L0
82879. We flushed at least 25 files
82880. This test will set a maximum allowed space for the DB, then it will keep filling the DB until the limit is reached and bg_error_ is set. When bg_error_ is set we will verify that the DB size is greater than the limit.
82881. disallow trivial move
82882. Create 1MB sst file
82883. Compaction must have deleted some files
82884. Check that compressions occur and are counted when compression is turned on
82885. Check that compressions do not occur when turned off
82886. pick arbitrary ticker and histogram. On first iteration they're zero because db is unused. On second iteration they're zero due to Reset().
82887. The Put() makes some of the ticker/histogram stats nonzero until we Reset().
82888. compressible string

82918. force a flush to make sure that no records are read from memtable
82919. skip "Otest"
82920. Now seek to the same key. The iterator should remain in the same position.
82921. should still be true after compaction
82922. namespace rocksdb
82923. Write rows with keys 00000, 00002, 00004 etc.
82924. This keeps track of the number of times NeedToSeekImmutable() was true.
82925. Sets iterate_upper_bound and verifies that ForwardIterator doesn't call Seek() on immutable iterators when target key is >= prev_key and all iterators, including the memtable iterator, are over the upper bound.
82926. Not valid since "21" is over the upper bound.
82927. Introduction of SyncPoint effectively disabled building and running this test in Release build. which is a pity, it is a good test
82928. Seek(0102) shouldn't find any records since 0202 has a different prefix
82929. 1st L0 file
82930. 2nd L0 file
82931. write a single record, read it using the iterator, then delete it
82932. !defined(ROCKSDB_LITE)
82933. make sure we can read all new records using the existing iterator
82934. we either see the entry or it's not in cache
82935. Seek to 13. This should not require any immutable seeks.
82936. Seek to 00001. We expect to find 00002.
82937. write many more records
82938. add a record and check that iter can see it
82939. level 1: [20, 25] [35, 40] level 2: [10 - 15] [45 - 50] level 3: [20, 30, 40] Previously there is a bug in tailing_iterator that if there is a gap in lower level, the key will be skipped if it is within the range between the largest key of index n file and the smallest key of index n+1 file if both file fit in that gap. In this example, 25 < key < 35 <https://github.com/facebook/rocksdb/issues/1372>
82940. Add another key to the memtable.
82941. Entry is already in cache, lookup will remove the element from lru
82942. Small write buffer
82943. ignore merge for now (*map_)[key.ToString()] = value.ToString();
82944. 3GB value 8MB key
82945. Test for check of prefix_extractor when hash index is used for block-based table
82946. Produce two L0 files with overlapping ranges.
82947. compact it three times
82948. **comment:** Test max_bytes_for_level_multiplier and max_bytes_for_level_base. Now, reduce both multiplier and level base, After filling enough data that can fit in L1 - L3, we should see L1 size reduces to 128KB from 256KB which was asserted previously. Same for L2.
 label: code-design
82949. Trigger reseek
82950. Start threads
82951. put some data
82952. find the new manifest file. assert that this manifest file is the same one as in the previous snapshot. But its size should be larger because we added an extra key after taking the previous snapshot.
82953. Generating 360KB in Level 2
82954. our clients require that GetLiveFiles returns files with "/" as first character!
82955. Unblock background threads
82956. Do a memtable compaction. Before bug-fix, the compaction would not detect the overlap with level-0 files and would incorrectly place the deletion in a deeper level.
82957. If thread tracking is not enabled, compaction count should be 0.
82958. 2nd round: flush and put a new value in memtable.
82959. Within (0.5, 1.5) of 4MB.
82960. Check if deletion worked.
82961. the second half of the test involves in random failure of file creation.
82962. Release sync calls
82963. Create 1 more file to trigger TTL compaction. The old files are dropped.
82964. Block background threads
82965. skip as HashCuckooRep does not support snapshot
82966. Now there is a file in L1.
82967. Only allow one compactin going through.
82968. table with xxhash checksum
82969. Fill levels 1 and 2 to disable the pushing of new memtables to levels > 0.
82970. only 5 files should survive
82971. Initialize state
82972. skip cuckoo hash as it does not support snapshot.
82973. ROCKSDB_USING_THREAD_STATUS
82974. iter == 0 -- leveled iter == 1 -- leveled, but throw in a flush between two levels compacting iter == 2 -- universal

82975. We need the 2nd write to trigger delay. This is because delay is estimated based on the last write size which is 0 for the first write.
82976. Now there is one L1 file (around 90KB) which exceeds 50KB base by 40KB L2 size is 360KB, so the estimated level fanout 4, estimated pending compaction is around 200KB triggering soft_pending_compaction_bytes_limit
82977. TEST_FlushMemTable() is not supported in ROCKSDB_LITE
82978. Block compaction again
82979. Delete archival files.
82980. Create 3 L0 files, making score of L0 to be 3.
82981. Start with 200MB/s
82982. Check that the writer thread counter is \geq the counter in the value
82983. Compaction range falls after files
82984. Github issue #595 Large write batch with column families
82985. Check that there are no extra characters.
82986. 20K 1.5MB
82987. Stop the threads and wait for them to finish
82988. **comment:** * This test is not reliable enough as it heavily depends on disk behavior. * Disable as it is flaky.
label: test
82989. only the non-default column family has non-matching comparator
82990. Check sizes across recovery by reopening a few times
82991. Compact more often
82992. each column family will have 5 thread, each thread generating 2 memtables. each column family should end up with 10 table files
82993. Now there is one L1 file (around 60KB) which exceeds 50KB base by 10KB Given level multiplier 10, estimated pending compaction is around 100KB doesn't trigger soft_pending_compaction_bytes_limit
82994. copy these files to a new snapshot directory
82995. Record the number of compactations at a time.
82996. Put
82997. Block sync calls
82998. **comment:** ApproximateOffsetOf() is not yet implemented in plain table format.
label: requirement
82999. **comment:** Test level0_stop_writes_trigger. Clean up memtable and L0. Block compaction threads. If continue to write and flush memtables. We should see put stop after 8 memtable flushes since level0_stop_writes_trigger = 8
label: code-design
83000. once the data has been flushed, we are able to get the data when kPersistedTier is used.
83001. now it's done
83002. returns false if the calling-Test should be skipped
83003. (Single) delete hidden by a put
83004. Compaction related options
83005. Compact away the placeholder files we created initially
83006. Test with TTL + Intra-L0 compactions.
83007. Fill one mem table
83008. inf
83009. Required if inheriting from testing::WithParamInterface<>
83010. Each file contains a different key which will be dropped later.
83011. Skip HashCuckooRep as it does not support single delete. FIFO and universal compaction do not apply to the test case. Skip MergePut because merges cannot be combined with single deletions.
83012. Insert 400KB. Some data will be compressed
83013. iter - 0 with 7 levels iter - 1 with 3 levels
83014. **comment:** After base level turn L4->L3, L3 becomes LZ4 and L4 becomes Zlib
label: code-design
83015. Test report_bg_io_stats
83016. Test disable_auto_compactions Compaction thread is unblocked but auto compaction is disabled. Write 4 L0 files and compaction should be triggered. If auto compaction is disabled, then TEST_WaitForCompact will be waiting for nothing. Number of L0 files do not change after the call.
83017. generate one more file in level-0, and should trigger level-0 compaction
83018. **comment:** Short sometimes to encourage collisions
label: code-design
83019. 10KB
83020. Decrease buffer size below current usage
83021. Test compression sanity check
83022. 500KB
83023. Block flush thread and disable compaction thread
83024. # rate limiting with 0.7 x threshold
83025. 1 hour
83026. These writes will be slowed down to 1KB/s
83027. writing 96 x 64KB \Rightarrow 6 * 1024KB (L1 + L2) = (1 + 4) * 1024KB
83028. 1st round: put but not flush
83029. After PinnableSlice destruction element is added back in LRU
83030. The first sync point is to make sure there's one flush job running when we perform VerifyOperationCount().
83031. 2MB 2MB
83032. Test max_write_buffer_number Block compaction thread, which will also block the flushes because max_background_flushes == 0, so flushes are getting executed by the compaction thread
83033. Only the new 10 files remain.
83034. Promote L0 level to L2.
83035. Insert 5 tasks to low priority queue and 5 tasks to high priority queue
83036. Check DB is not in read-only state.
83037. Destroy previous versions if they exist. Using the long way.
83038. Compact just the new range
83039. Slow down twice. One for memtable switch and one for flush finishes.
83040. Skip HashCuckooRep as it does not support single delete. FIFO and universal compaction do not apply to the test case. Skip MergePut because single delete does not get removed when it encounters a merge.
83041. Multiget
83042. The Put Phase.
83043. Skip HashCuckooRep as it does not support single delete. FIFO and universal compaction do not apply to the test case. Skip MergePut because single delete does not get removed when it encounters a merge.
83044. Generate and flush a file about 20KB.
83045. Step 4: Wait for compaction to finish
83046. repeat the test with differet number of high / low priority threads
83047. Multi-element batch
83048. Increase
83049. Create 10 more files. The old 5 files are dropped as their ttl expired.

83050. namespace
83051. Delete databases
83052. Make rocksdb busy
83053. Try up to 60 seconds.
83054. Block compaction
83055. Place a table at level last-1 to prevent merging with preceding mutation
83056. Don't trigger compact/slowdown/stop
83057. 110KB
83058. release file snapshot
83059. Occasionally sleep a while
83060. Github issue #596
83061. For DB instances that use the hash index + block-based table, the iterator will be invalid right when seeking a non-existent key, right than return a key that is close to it.
83062. look at the new live files after we added an 'extra' key and after we took the first snapshot.
83063. Let them run for a while
83064. Generating 360KB in Level 3
83065. 1MB 4MB
83066. the oldest wal should now be getting_flushed
83067. 100KB
83068. Multi-threaded test:
83069. With Intra-L0 compaction, out of 10 files, 6 files will be compacted to 1 (due to level0_file_num_compaction_trigger = 6). So total files = 1 + remaining 4 = 5.
83070. only 2 memtables will be alive, so logs_to_free needs to always be below 2
83071. **comment:** TODO(yhchiang): adding assert to verify each compaction stage.
label: test
83072. Reopen it without prefix extractor, make sure everything still works. RocksDB should just fall back to the binary index.
83073. first iteration -- auto compaction second iteration -- manual compaction
83074. Test that shows the fall back to size-based FIFO compaction if TTL-based deletion doesn't move the total size to be less than max_table_files_size.
83075. nonoverlapping with the file on level 0
83076. Write approximately 100MB of "B" values
83077. Group commit test:
83078. Test max_bytes_for_level_base Increase level base size to 256KB and write enough data that will fill L1 and L2. L1 size should be around 256KB while L2 size should be around 256KB x 4.
83079. they are either both ok or both not-found
83080. flush should happen here
83081. Put until writes are stopped, bounded by 256 puts. We should see stop at ~128KB
83082. DEL eliminated, but v1 remains because we aren't compacting that level (DEL can be eliminated because v2 hides v1).
83083. Test to check whether flushing preserves a single delete hidden behind a put.
83084. do not compress L0
83085. Half of the time directly use WriteBatch. Half of the time use WriteBatchWithIndex.
83086. This second sync point is to ensure the flush job will not be completed until we already perform VerifyOperationCount().
83087. Test with large TTL + Intra-L0 compactions. Files dropped based on size, as ttl doesn't kick in.
83088. Wait 100 milliseconds for they are scheduled.
83089. writing 20 x 64KB = 10 x 128KB (L1 + L2 + L3) = (1 + 2 + 4) * 128KB
83090. **comment:** make sure the thread is not done
label: requirement
83091. Read a value and verify that it matches the pattern written above and that writes to all column families were atomic (unique_id is the same)
83092. Change the number of threads in high / low priority pool.
83093. We must have at most one file per level except for level-0, which may have up to kL0_StopWritesTrigger files.
83094. About 200KB/s limited rate
83095. Since no flushes and compactions have run, the db should still be in the same state even after considerable time has passed.
83096. Do we own map_
83097. Inserting a new entry would create a new mem table, triggering slow down.
83098. Write values of the form <key, my id, counter, cf, unique_id>. into each of the CFs We add some padding for force compactions.
83099. **comment:** ApproximateOffsetOf() is not yet implemented in plain table format, which is used by Size(). skip HashCuckooRep as it does not support snapshot
label: requirement
83100. Compact all files.
83101. Write 120KB (12 values, each 10K)
83102. Save a snapshot from each DB this time that we'll use next time we compare things, to make sure the current state is preserved with the snapshot
83103. here we expect some of the Put fails.
83104. Check that we process level-0 files in correct order. The code below generates two level-0 files where the earlier one comes before the later one in the level-0 file list since the earlier one has a smaller "smallest" key.
83105. CURRENT, MANIFEST, OPTIONS, *.sst files (one for each CF)
83106. Try if CreateColumnFamily also fails
83107. 1MB
83108. Does not exist, and create_if_missing == true: OK
83109. **comment:** The existing memtable became eligible for flush when we reduced its capacity to 64KB. Two keys need to be added to trigger flush: first causes memtable to be marked full, second schedules the flush. Then we should have a 128KB L0 file, a 64KB L0 file, and a memtable with just one key.
label: code-design
83110. This makes sure at least one compaction is running.
83111. Fill memtable Trigger flush
83112. Not Supported directly
83113. Start from scratch and disable compaction/flush. Flush can only happen during compaction but trigger is pretty high
83114. Advance sequence number one more
83115. Compact all
83116. very small only two memtables allowed ==> only two log files
83117. Verify the total number of threads
83118. get a file snapshot
83119. **comment:** Cleaning up
label: code-design
83120. **comment:** Insert more than 80K. L4 should be base level. Neither L0 nor L4 should be compressed, so total data size should be more than 80K.
label: code-design
83121. This test may fail because of a legit case that multiple L0 files are trivial moved to L1.
83122. repeat the test with multiple column families
83123. No files in L1
83124. Create 3 L0 files, making score of L0 to be 3
83125. new wal should have been created
83126. (A)

83128. all flushes should now do nothing because their CF is dropped

83129. Estimate the total sleep time fall into the rough range.

83130. Single deletes that encounter the matching put in a flush should get removed.

83131. 10 KB

83132. Check that it is not supported with max_open_files != -1.

83133. When base level is L4, L4 is LZ4.

83134. Enable auto compaction and perform the same test, # of L0 files should be reduced after compaction.

83135. Make files spanning the following ranges in level-0: files[0] 200 .. 900 files[1] 300 .. 500 Note that files are sorted by smallest key.

83136. make sure we can re-open it.

83137. Schedule a sleeping task.

83138. No reseek

83139. Decrease

83140. **comment:** Speed up the test
label: test

83141. This makes sure a compaction won't be scheduled until we have done with the above Put Phase.

83142. Wait to ensure the all threads has been registered

83143. Setup databases

83144. this has to start a flush. if flushes are blocked, this will try to create 3 memtables, and that will fail because max_write_buffer_number is 2

83145. The existing memtable inflated 64KB->128KB when we invoked SetOptions(). Write 192KB, we should have a 128KB L0 file and a memtable with 64KB data.

83146. namespace rocksdb

83147. Make sparse update

83148. Still expect finding the value as its delete has not yet being flushed.

83149. Check format

83150. It should be compacted to no more than 20 files.

83151. **comment:** The following condition prevents a race condition between flush jobs acquiring work and this thread filling up multiple memtables. Without this, the flush might produce less files than expected because multiple memtables are flushed into a single L0 file. This race condition affects assertion (A).
label: code-design

83152. Stop trigger = 8

83153. But everything before we simulate the failure-test should succeed.

83154. If rocksdb does not do the correct job, internal assert will fail here.

83155. no need to call this

83156. Size limit is still guaranteed.

83157. verify we have the latest successful update

83158. this checks that updates across column families happened atomically -- all unique ids are the same

83159. should not compact the level 0 file

83160. **comment:** Clean up L0
label: code-design

83161. Does exist, and error_if_exists == false: OK

83162. Compaction range falls before files

83163. Populate a different range

83164. this should fill up 2 memtables

83165. Test compaction trigger and target_file_size_base Reduce compaction trigger to 2, and reduce L1 file size to 32KB. Writing to 64KB L0 files should trigger a compaction. Since these 2 L0 files have the same key range, compaction merge them and should result in 2 32KB L1 files.

83166. Read directly from persisted data.

83167. pool size 2, total task 4. Queue size should be 2.

83168. Delay both flush and compaction

83169. If we compact: Put(A, v1) Snapshot SingleDelete(A) Put(A, v2) We do not want to end up with: Put(A, v1) Snapshot Put(A, v2) Because a subsequent SingleDelete(A) would delete the Put(A, v2) but not Put(A, v1), so Get(A) would return v1.

83170. record the number and the size of the latest manifest file

83171. Delete

83172. Zero if not including mem table

83173. # rate limiting with half of the raw_rate

83174. Make sure that Flushes can proceed in parallel with CompactRange()

83175. Step 3: read a bunch of times

83176. update the latest successful put

83177. reopen and reverify we have the latest successful update

83178. Periodically re-use the same key from the previous iter, so we have multiple entries in the write batch for the same key

83179. **comment:** Use a small number to ensure a large delay that is still effective when we do Put TODO(myabandeh): this is time dependent and could potentially make the test flaky
label: test

83180. Arrange for the following to happen: * sstable A in level 0 * nothing in level 1 * sstable B in level 2 Then do enough Get() calls to arrange for an automatic compaction of sstable A. A bug would cause the compaction to be marked as occurring at level 1 (instead of the correct level 0).

83181. these keys should be deleted in previous compaction

83182. now it should compact the level 0 file

83183. Just to make sure that we are in the same state even after sleeping.

83184. Check that FIFO-with-TTL is supported only with BlockBasedTableFactory.

83185. **comment:** Sleep for 2 hours -- which is much greater than TTL. Note: Couldn't use SleepForMicroseconds because it takes an int instead of uint64_t. Hence used addon_time_directly. env_->SleepForMicroseconds(2 * 60 * 60 * 1000 * 1000);
label: code-design

83186. Now there is one L1 file but doesn't trigger soft_rate_limit The L1 file size is around 30KB.

83187. 0 because GetApproximateSizes() does not account for memtable space

83188. Verify the number of low-priority threads

83189. Unblock

83190. Clear memtable and make new option effective

83191. Suppose there is: small amount of data with prefix A large amount of data with prefix B small amount of data with prefix C and that recent updates have made small changes to all three prefixes. Check that we do not do a compaction that merges all of B in one shot.

83192. Does exist, and error_if_exists == true: error

83193. create a DB with block prefix index

83194. Most intervals should've been drained (interval time is 100ms, elapsed is micros)

83195. Fails because L1 is non-empty.

83196. do not compress L0 and L1

83197. Fails because L0 has overlapping files.

83198. Test paranoid_file_checks already done in db_block_cache_test

83199. Test max_sequential_skip_in_iterations

83200. overwrite one key, this key should not appear in the snapshot

83201. First three 110KB files are not going to level 2 After that, (100K, 200K)
83202. Enable time profiling
83203. Write 3 files that have the same key range. Since level0_file_num_compaction_trigger is 3, compaction should be triggered. The compaction should result in one L1 file
83204. as data has not yet being flushed, we expect not found.
83205. Test to make sure that all files with expired ttl are deleted on next manual compaction.
83206. ROCKSDB_LITE
83207. Disable because not all platform can run it. It requires more than 9GB memory to run it, With single allocation of more than 3GB.
83208. sanity check
83209. expecting one single L0 to L1 compaction
83210. Create 3 L0 files, making score of L0 to be 3, higher than L0.
83211. **comment:** Step 2: clear level 1 if necessary.
 label: code-design
83212. Wake up sleep task to enable compaction to run and waits for it to go to sleep state again to make sure one compaction goes through.
83213. DEL kept: "last" file overlaps
83214. **comment:** TODO(sanjay): Test Get() works
 label: test
83215. Put values on second level (so that they will not be in the same compaction as the other operations.
83216. 150KB
83217. Make sure data in files in L3 is not compacted by removing all files in L4 and calculate number of rows
83218. Not very large
83219. Sleep for 2 hours -- which is much greater than TTL.
83220. Check that FIFO-with-TTL is not supported with max_open_files != -1.
83221. Flush the file. File size is around 30KB.
83222. shrink level base so L2 will hit soft limit easier.
83223. Assuming each files' metadata is at least 50 bytes/
83224. Now reduce level0_stop_writes_trigger to 6. Clear up memtables and L0. Block compaction thread again. Perform the put and memtable flushes until we see the stop after 6 memtable flushes.
83225. foo => v1 is now in last level
83226. Generate and flush a file about 10KB.
83227. compressible string
83228. Expect same result in multiget
83229. Test write_buffer_size
83230. We expect that all the files were trivially moved from L0 to L2
83231. Arrange to have multiple files in a non-level-0 level.
83232. iter 0 -- zlib iter 1 -- bzip2 iter 2 -- lz4 iter 3 -- lz4HC iter 4 -- xpress
83233. pool size 3, total task 4. Queue size should be 1.
83234. Step 1: First place sstables in levels 0 and 2
83235. Moves to level last-2
83236. Test to make sure that all files with expired ttl are deleted on next automatic compaction.
83237. NewMemEnv returns nullptr in ROCKSDB_LITE since class InMemoryEnv isn't defined.
83238. Key has not yet been written
83239. Does not exist, and create_if_missing == false: error
83240. assert that nothing makes it to disk yet.
83241. Allow some expansion from metadata

83284. arg
83285. The first dependency enforces Marker can be loaded before MarkedPoint. The second checks that thread 1's MarkedPoint should be disabled here. Execution order:
| Thread 1 | Thread 2 | || Marker || MarkedPoint || | Thread1First | ||| MarkedPoint |
83286. only index/filter were added
83287. column_family_name -> column_family_id map (provided to WALFilter)
83288. We expect the record with apply_option_for_record_index to be not found.
83289. Make sure that we wrote enough to check all 7 levels
83290. Processing option that is requested to be applied at the given index
83291. We want to make sure to call this callback only once
83292. default column-family, only post_flush keys are expected
83293. **comment:** GetUniqueIdFromFile is not implemented
label: requirement
83294. On Recovery we should only find the second batch applicable to default CF But both batches applicable to pikachu CF
83295. Create a test filter that would apply wal_processing_option at the first record
83296. Read keys/values randomly and verify that reported read amp error is less than 2%
83297. Get base cache values
83298. ROCKSDB_LITE
83299. Use Snappy except for bottommost level use ZLib
83300. Triggering flush in DB2.
83301. Infinite for full compaction.
83302. While the compaction is running, we will create 2 new files that can fit in L2, these 2 files will be moved to L2 and overlap with the running compaction and break the LSM consistency.
83303. Fill memtable Trigger flush
83304. Start a non-exclusive manual compaction in a bg thread
83305. Miss and hit count should remain the same, they're all pinned.
83306. Ensure that given keys don't exist
83307. Filter is passed as a const object for RocksDB to not modify the object, however we modify it for our own purpose here and hence cast the constness away.
83308. Ensure that expected keys exists and not expected keys don't exist after recovery
83309. Reopen database. If max_open_files is set as -1, table readers will be preloaded. This will trigger a BlockBasedTable::Open() and prefetch L0 index and filter.
Level 1's prefetching is disabled in DB::Open()
83310. Create 3 batches with two keys each
83311. If max_open_files is -1, we have pinned index and filter in Rep, so there will not be changes in index and filter misses or hits. If max_open_files is not -1, Get()
will open a TableReader and prefetch index and filter.
83312. Callback is only executed once
83313. pikachu column-family, all keys are expected
83314. Hold NotifyOnCompactionCompleted in the unlock mutex section
83315. Write 10 random files
83316. After reopen, cache miss are increased by one because we read (and only read) filter and index on L0
83317. /dev/shm dont support getting a unique file id, this mean that running this test on /dev/shm will fail because lru_cache will load the blocks again regardless of them
being already in the cache
83318. Do some more writes
83319. bytes read for user iterator shouldn't count against the rate limit.
83320. Reopen without filter, now reopen should succeed - previous attempt to open must not have altered the db.
83321. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root
directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). Copyright (c) 2011 The LevelDB Authors. All rights reserved. Use of

83322. Compaction pressure should trigger since 6 files
83323. Wait for compaction to be triggered
83324. 10KiB
83325. Current record index, incremented with each record encountered.
83326. Figure out last level with files
83327. compaction input has 512KB data
83328. This ensures that there is no ref to block cache entries
83329. this is never hit Use a write buffer total size so that the soft limit is about 105000.
83330. Clear "DBImpl::BGWorkCompaction" SYNC_POINT since we want to hold it again at DBTest2::CompactionStall:::1
83331. column_family_name -> keys_found_in_wal map We store keys that are applicable to the column_family during recovery (i.e. aren't already flushed to SST
file(s)) for verification against the keys we expect.
83332. this should be read from L0
83333. This manual compaction conflict with the other manual compaction so it should wait until the first compaction finish
83334. Add a key to memtable
83335. **comment:** Error between reported read amp and real read amp should be less than 2%
label: code-design
83336. namespace
83337. Iter2: Read half the DB, Read odd keys Key(1), Key(3), Key(5), Key(7), Key(9), ...
83338. Index at which to start changing records
83339. get base cache values
83340. Memtable-only iterator (read_tier=kMemtableTier); data not flushed yet.
83341. Block compaction
83342. Ensure that expected keys exist
83343. verify that handles_[0] only has post_flush keys while handles_[1] has pre and post flush keys
83344. When compact from Ln -> Ln+1, cut a file if the file overlaps with more than three files in Ln+1.
83345. this should be read from L1 the file is opened, prefetching results in a cache filter miss the block is loaded and added to the cache, then the get results in a cache hit
for L1 When we have infinite max_files, there is still cache miss because we have reset the block cache
83346. Reopen database with option to use WAL filter
83347. Index at which to apply wal_processing_option_ At other indexes default wal_processing_option::kContinueProcessing is returned.
83348. Make sure to use any custom env that the test is configured with.
83349. Make sure we read every thing in the DB (which is smaller than our cache)
83350. Use Snappy everywhere
83351. takes roughly one second, split into 100 x 10ms intervals. Each interval permits 5.12KB, which is smaller than the block size, so this test exercises the code for
chunking reads.
83352. 4 Files in L0
83353. Trivial move 2 files to L1
83354. Without hitting the threshold, no flush should trigger.
83355. **comment:** Huge block cache to make it easier to calculate read amplification
label: code-design
83356. column_family_id -> log_number map (provided to WALFilter)

83357. Batch to insert keys in
83358. Run a manual compaction that will compact the 2 files in L2 into 1 file in L2
83359. small write buffer
83360. Before flushing point lookups
83361. unhandled case
83362. Trivial move 2 files to L2
83363. While the compaction is running, we will create 2 new files that can fit in L1, these 2 files will be moved to L1 and overlap with the running compaction and break the LSM consistency.
83364. flush all data from memtable so that reads are from block cache
83365. Test with all WAL processing options
83366. Include the explicit prefetch of the footer in direct I/O case.
83367. namespace rocksdb
83368. move this table to L1
83369. Number of keys to add in the new batch
83370. Compute which keys we expect to be found and which we expect not to be found after recovery.
83371. Create a test filter that would add extra keys
83372. high compression ratio
83373. If max_open_files is not -1, we do not preload table readers, so there is no change.
83374. Write given keys in given batches
83375. After flushing point lookups
83376. In case of corruption we can turn off paranoid_checks to reopen database
83377. Test that the stats GetMapProperty API reporting 1 file in L2
83378. !ROCKSDB_LITE
83379. we expect all records to be processed
83380. fairness
83381. no block cache
83382. Trigger another flush. This time "dobbynia". "pikachu" should not be flushed, although it was never flushed.
83383. should be slightly above 512KB due to non-data blocks read. Arbitrarily chose 1MB as the upper bound on the total bytes read.
83384. default column family doesn't have block cache
83385. In this case, cache miss will be increased by one in BlockBasedTable::Open() because this is not in DB::Open() code path so we will prefetch L1's index and filter.
Cache hit will also be increased by one because Get() will read index and filter from the block cache prefetched in previous Open() call.
83386. rate_bytes_per_sec
83387. Create some data and flush "default" and "nikitich" so that they are newer CFs created.
83388. LZ4_VERSION_NUMBER >= 10400
83389. this is the real limit
83390. Insert to DB2
83391. We expect records beyond apply_option_for_record_index to be not found.
83392. Destroy old statistics obj that the blocks in lru_cache are pointing to
83393. compressed
83394. Output files to L1 are cut to three pieces, according to options.max_compaction_bytes
83395. create new table at L0
83396. make sure all background compaction jobs can be scheduled
83397. reset block cache
83398. 1M
83399. IOS_SOLARIS
83400. Trigger a flush on cf2
83401. Create a new table.
83402. In infinite max files case, there's a cache miss in executing Get() because index and filter are not prefetched before.
83403. The total soft write buffer size is about 105000
83404. Avoid undeterministic value by malloc_usable_size(); Force arena block size to 1
83405. uncompressed
83406. Iter1: Read half the DB, Read even keys Key(0), Key(2), Key(4), Key(6), Key(8), ...
83407. Use different compression algorithms for different levels but always use Zlib for bottommost level
83408. Run a manual compaction that will compact the 2 files in L1 into 1 file in L2
83409. Read amp is on average 100% since we read all what we loaded in memory
83410. refill_period_us
83411. Hit the write buffer limit again. "default" will have been flushed.
83412. Add three more small files that overlap with the previous file
83413. No flush should trigger
83414. Flush default column-family
83415. Ensure that all keys exist before change_records_from_index_. And after that index only single key exists as our filter adds only single key for each batch
83416. this should be read from L0 so cache values don't change
83417. Triggering to flush another CF in DB1
83418. Use the statistics object that we just created
83419. Make sure DB can be reopen with reduced number of levels, given no file is on levels higher than the new num_levels.
83420. empty vector
83421. index/filter blocks added to block cache right after table creation.
83422. Also test that the stats GetMapProperty API reporting the same result
83423. **comment:** Disable delta encoding to make it easier to calculate read amplification
label: code-design
83424. reopen database again to make sure previous log(s) are not used (even if they were skipped) reopn database with option to use WAL filter
83425. This snapshot will have sequence number 0 what is expected behaviour.
83426. Number of keys added to new batch
83427. Write 8MB (80 values, each 100K)
83428. this should be read from L1
83429. this is never hit
83430. Get() is issued after the first Put(), so it should see either "v1" or "v2".
83431. If the current record is applicable for column_family_id (i.e. isn't flushed to SST file(s) for column_family_id) add it to the cf_wal_keys_map for verification.
83432. This ensures that db does not ref anything in the block cache, so EraseUnRefEntries could clear them up.
83433. nothing should be returned using memtable-only iterator after flushing.
83434. Another 6 L0 files to trigger compaction again
83435. Wait for another compaction to be triggered
83436. Trigger a flush. Flushing "nikitich".
83437. First iteration: compress without preset dictionary Second iteration: compress with preset dictionary To make sure the compression dictionary was actually used, we verify the compressed size is smaller in the second iteration. Also in the second iteration, verify the data we get out is the same data we put in.
83438. Return the current option configuration.
83439. Destroy using last options
83440. This options optimize 2PC commit path

83441. Switch between different WAL settings
83442. Return a string that contains all key,value pairs in order, formatted like "(k1->v1)(k2->v2)".
83443. Prevent pushing of new sstables into deeper levels by adding tables that cover a specified range to all levels.
83444. Special Env used to delay background operations
83445. **comment:** Verify Iterator::Prev() Use a new iterator to make sure its status is clean.
 label: code-design
83446. Used to test InplaceUpdate
83447. namespace rocksdb
83448. Do n memtable compactions, each of which produces an sstable covering the range [small,large].
83449. Verify Iterator::Next()
83450. These options are not supported in ROCKSDB_LITE
83451. Verify ForwardIterator::Next()
83452. **comment:** Note: operator= is an unsafe approach here since it destructs shared_ptr in the same order of their creation, in contrast to destructors which destructs them in the opposite order of creation. One particular problem is that the cache destructor might invoke callback functions that use Option members such as statistics. To work around this problem, we manually call destructor of table_facotry which eventually clears the block cache.
 label: code-design
83453. Destroy it for not alternative WAL dir is used.
83454. If previous value is nullptr or delta is > than previous value, sets newValue with delta If previous value is not empty, updates previous value with 'b' string of previous value size - 1.
83455. Verify Iterator::Seek()
83456. default argument means copy everything
83457. Tailing iterator
83458. ROCKSDB_LITE
83459. **comment:** TODO(3.13) -- test more options
 label: test
83460. mmap reads should be orthogonal to WalDir setting, so we piggyback to this option config to test mmap reads as well
83461. 50 bytes
83462. **comment:** this redundant copy is to minimize code change w/o having lint error.

83514. 10s

83515. 1s

83516. After number of inserts exceeds `num_entries_flush` in a mem table, trigger flush.

83517. Switch to a fresh database with the next option configuration to test. Return false if there are no more configurations to test.

83518. Simulate non-writable file system while this pointer is non-nullptr

83519. SyncPoint is not supported in Released Windows Mode.

83520. Insert key into the list. REQUIRES: nothing that compares equal to key is currently in the list.

83521. Switch between different WAL-related options.

83522. Write 3 files while 1st compaction is held These 3 files have different sizes to avoid compacting based on size_ratio

83523. Tests universal compaction with trivial move enabled

83524. Hold the 1st compaction from finishing

83525. All files at level 0 will be compacted into a single one.

83526. Make sure bloom filter is used at least once.

83527. Compact all to level 0

83528. (1, 4, 8) -> (5, 8)

83529. Write 120KB (12 values, each 10K)

83530. expect ok and verify the compacted files no longer exist.

83531. Compact all files into 1 file and put it in L4

83532. 1MB

83533. Suppose each file flushed from mem table has size 1. Now we compact (level0_file_num_compaction_trigger+1)=4 files and should have a big file of size 4.

83534. block compaction from happening

83535. Write 8 files while 1st compaction is held These 8 files have different sizes to avoid compacting based on size_ratio

83536. Pick the first and the last file, expect everything is compacted into one single file.

83537. Before compaction, we have 4 files at level 0, with size 4, 2.4, 1, 1. After compaction, we should have 3 files, with size 4, 2.4, 2.

83538. Trigger compaction if size amplification exceeds 110%

83539. Stage 1: Generate a set of files at level 0, but don't trigger level-0 compaction.

83540. When we start for the compaction up to (2 4 8), the latest compressed is not compressed.

83541. Disable size amplification compaction

83542. Stop SyncPoint and destroy the DB and reopen it again

83543. Make sure bloom filter is used for all but the last L0 file when looking up a non-existent key that's in the range of all L0 files.

83544. First three 110KB files are not going to second path. After that, (100K, 200K)

83545. Wait for the 1st background compaction process to start

83546. Insert more keys

83547. Another 110KB triggers a compaction to 400K file to second path

83548. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). 83549. **comment:** Stage 2: Now we have one file at level 0, with size 4. We also have some data in mem table. Let's continue generating new files at level 0, but don't trigger level-0 compaction. First, clean up memtable before inserting new data. This will generate a level-0 file, with size around 0.4 (according to previously written data amount).

label: code-design

83550. Write 100KB file. And immediately it should be compacted to one file.

83551. no_wait

83552. 1KB

83553. (1, 2, 8) -> (3, 8)

83554. each value is 10K

83555. When we start for the compaction up to (2 4 8), the latest compressed is compressed given the size ratio to compress.

83556. namespace

83557. This time we will trigger a compaction because of size ratio and another compaction because of number of files that are not compacted greater than 7

83558. !defined(ROCKSDB_LITE)

83559. Hold the 1st and 2nd compaction from finishing

83560. Make sure we don't trigger a problem if the trigger condition is given to be 0, which is invalid.

83561. Wait for the 2nd background compaction process to start

83562. **comment:** Regression test for extra compactions scheduled. Once enough compactions have been scheduled to bring the score below one, we should stop scheduling more; otherwise, other CFs/DBs may be delayed unnecessarily.

label: code-design

83563. Before compaction, we have 4 files at level 0, with size 4, 0.4, 1, 1. After compaction, we should have 2 files, with size 4, 2.4.

83564. Config universal compaction to always compact to one single sorted run.

83565. Generate 3 overlapping files

83566. wait for the full compaction to be picked before adding files intended for the second one.

83567. Write 110KB (11 values, each 10K)

83568. Delete archival files.

83569. Generate two files in Level 0. Both files are approx the same size.

83570. (1, 1, 8) -> (2, 8)

83571. 105KB

83572. Reopen and check.

83573. namespace rocksdb

83574. Test that checks trivial move in universal compaction

83575. Compaction to non-L0 has happened.

83576. 100KB

83577. There should only be one picked compaction as the score drops below one after the first one is picked.

83578. Big size

83579. Fail when compacting to an invalid path ID

83580. Write 100KB

83581. the full (bottom-pri) compaction waits until a partial (low-pri) compaction has started to verify they can run in parallel.

83582. expect fail since universal compaction only allow L0 output

83583. The same queries will not trigger bloom filter

83584. Stage 5: Now we have 4 files at level 0, with size 4, 2.4, 2, 1. Let's generate a new file of size 1.

83585. (1, 2, 4) -> (3, 4)

83586. Stage 3: Now we have 2 files at level 0, with size 4 and 2.4. Continue generating new files at level 0.

83587. Need to restart it once to remove higher level records in manifest.

83588. use no_wait above because that one waits for flush and compaction. We don't want to wait for compaction because the full compaction is intentionally blocked while more files are flushed.

83589. Compacting the first four files was enough to bring the score below one so there's no need to schedule any more compactions.

83590. 100KB 32KB

83591. Query set of non existing keys

83592. Final reopen

83593. The third compaction (2 4) is compressed since this time it is (1 1 3.2) and 3.2/5.2 doesn't reach ratio.

83594. Level-0 compaction is triggered, but no file will be picked up.
83595. The second compaction (4) is compressed
83596. 114KB
83597. 105KB 4KB 32KB trigger compaction if there are ≥ 4 files
83598. Generate one more file at level-0, which should trigger level-0 compaction.
83599. Write 100KB (100 values, each 1K)
83600. Flush whatever is remaining in memtable. This is typically small, which should not trigger size ratio based compaction but will instead trigger size amplification.
83601. for single-level universal, everything's bottom level so nothing should be executed in bottom-pri thread pool.
83602. 32KB trigger compaction if there are ≥ 4 files
83603. Stage 4: Now we have 3 files at level 0, with size 4, 2.4, 2. Let's generate a new file of size 1.
83604. **comment:** TODO(kailiu) The tests on UniversalCompaction has some issues: 1. A lot of magic numbers ("11" or "12"). 2. Made assumption on the memtable flush conditions, which may change from time to time.
label: code-design
83605. 200KB
83606. The first compaction (2) is compressed.
83607. Full compaction to DB path 0
83608. Unblock compaction and wait it for happening.
83609. Write 7 files to trigger compaction
83610. (1, 4)
83611. Stage 3: Now we have 3 files at level 0, with size 4, 0.4, 2. Generate one more file at level-0, which should trigger level-0 compaction.
83612. (1, 3, 8) \rightarrow (4, 8)
83613. Verify that size amplification did occur
83614. (1,1,4) \rightarrow (2, 4)
83615. First compaction should output to bottom level. Second should output to L0 since older L0 files pending compaction prevent it from being placed lower.
83616. 105KB 4KB 32KB
83617. allow_ingest_behind increases number of levels while sanitizing.
83618. (1, 3, 4) \rightarrow (8)
83619. Before compaction, we have 4 files at level 0, with size 4, 0.4, 1, 1. After compaction, we should have 3 files, with size 4, 0.4, 2.
83620. Delay every compaction so multiple compactations will happen.
83621. Stage 2: reopen with universal compaction, num_levels=4
83622. Stage 3: Revert it back to one level and revert to num_levels=1.
83623. Stage 1: open a DB with universal compaction, num_levels=1
83624. (1, 8)
83625. again both values should be present.
83626. 4 memtable are not flushed, 1 sst file
83627. Reopen, insert and flush.
83628. First 4 keys goes to separate SSTs + 1 more SST for 2 smaller keys
83629. Reopen twice and validate.
83630. Make sure that if we re-open with a small write buffer size that we flush table files in the middle of a large log file.
83631. Verify clean slate behavior
83632. Flush() triggers deletion of obsolete tracked files
83633. Check, that records for 'default', 'dobrynia' and 'pikachu' from first, second and third WALs went to the same SST. So, there is 6 SSTs: three for 'nikitich', one for 'default', one for 'dobrynia', one for 'pikachu'
83634. seq id 4
83635. verify
83636. Simulate a crash.
83637. Verify behavior
83638. fill with new date
83639. Manually corrupt the specified WAL
83640. New WAL file
83641. ROCKSDB_LITE
83642. Create corrupted WAL
83643. assert that we successfully recovered only from logs, even though we destroyed the DB
83644. Test scope: - We expect to open data store under all circumstances - We expect only data upto the point where the first error was encountered
83645. Destroy DB before destruct fault_env.
83646. Read back all the keys we wrote and return the number of keys found
83647. corrupt the wal
83648. Reopen DB. Check if WAL logs flushed.
83649. Corruption offset position
83650. len=%
83651. 1 SST for big key + 1 SST for small one
83652. Starting number for the WAL file name like 00010.log
83653. Write to new WAL file
83654. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). See the AUTHORS file for names of contributors.
83655. Create WAL files with values filled in
83656. Corrupt the WAL
83657. Insert some data without flush
83658. Prior to the fix, we may incorrectly recover "v5" with sequence id = 3.
83659. Since we will reopen DB with smaller write_buffer_size, each key will go to new SST file
83660. There are still 4 memtable not flushed, and 2 sst tables
83661. Append some more data.
83662. **comment:** On windows long is 32-bit
label: code-design
83663. Github issue 1339. Prior the fix we read sequence id from the first log to a local variable, then keep increase the variable as we replay logs, ignoring actual sequence id of the records. This is incorrect if some writes come with WAL disabled.
83664. Reopen DB. WAL logs should not be flushed this time.
83665. WAL file
83666. fill up the DB
83667. Test scope: - We expect to open the data store under all scenarios - We expect to have recovered records past the corruption zone
83668. Both value's should be present.
83669. manual flush and insert again
83670. make sure we can re-open it.
83671. Number of WAL files to generate
83672. Test scope: We don't expect the data store to be opened if there is any corruption (leading, middle or trailing -- incomplete writes or corruption)
83673. Moving this to SyncWAL before the actual fsync TEST_SYNC_POINT("DBWALTest::SyncWALNotWaitWrite:1");
83674. Keys to be written per WAL file

83675. Corruption offset
83676. In this test we are trying to do the following: 1. Create a DB with corrupted WAL log; 2. Open with avoid_flush_during_recovery = true; 3. Append more data without flushing, which creates new WAL log. 4. Open again. See if it can correctly handle previous corruption.
83677. Corrupt the wal
83678. seq id 1
83679. Recreate and fill the store with some data
83680. Recovery will fail if DB directory doesn't exist.
83681. Fill data for testing
83682. wal files
83683. Test with flush after recovery.
83684. No inserts => default is empty
83685. Create DB with multiple column families and multiple log files.
83686. namespace rocksdb
83687. Overwrite data with 'a' from offset for length len
83688. wal=
83689. this should ignore the log files, recovery should not happen again if the recovery happens, the same merge operator would be called twice, leading to incorrect results
83690. seq id 5
83691. Test without flush after recovery.
83692. Moving this to SyncWAL after actual fsync TEST_SYNC_POINT("DBWALTest::SyncWALNotWaitWrite:2");
83693. Make 'nikitich' memtable to be flushed
83694. Test scope: - We expect to open the data store when there is incomplete trailing writes at the end of any of the logs - We do not expect to open the data store for corruption
83695. Insert again and reopen
83696. Now the original WAL is in log_files[0] and should be marked for recycling. Verify full purge cannot remove this file.
83697. In https://reviews.facebook.net/D20661 we change recovery behavior: previously for each log file each column family memtable was flushed, even it wasn't empty.
Now it's changed: we try to create the smallest number of table files by merging updates from multiple logs
83698. Save data for comparison.
83699. Skip the test if DB won't open.
83700. force
83701. Test WAL recovery for the various modes available
83702. copy the logs to backup
83703. delete old files in backup_logs directory
83704. Memtable for 'nikitich' has flushed, new WAL file has opened 4 memtable still not flushed
83705. copy the logs from backup back to wal dir
83706. off=
83707. make it flush
83708. Reopen. Verify data.
83709. Make sure 'dobrynia' was flushed: check sst files amount
83710. Probe data for invariants
83711. 1 SST for all keys
83712. recover the DB
83713. For github issue #1303
83714. Fill up 'nikitich' one more time
83715. Verifies WAL files that were present during recovery, but not flushed due to avoid_flush_during_recovery, will be considered for deletion at a later stage. We check at least one such file is deleted during Flush().
83716. **comment:** Check at least the first WAL was cleaned up during the recovery.
label: code-design
83717. Force flush with allow_2pc.
83718. Size of the value
83719. !(defined(NDEBUG) || !defined(OS_WIN))
83720. Make 'dobrynia' to be flushed and new WAL file to be created
83721. test checksum failure or parsing
83722. Offset of corruption
83723. Windows disk cache behaves differently. When we truncate the original content is still in the cache due to the original handle is still open. Generally, in Windows, one prohibits shared access to files and it is not needed for WAL but we allow it to induce corruption at various tests.
83724. **comment:** Test for regression of WAL cleanup missing files that don't contain data for every column family.
label: code-design
83725. **comment:** Corruption style
label: code-design
83726. Insert more data.
83727. In https://reviews.facebook.net/D20661 we change recovery behavior: previously for each log file each column family memtable was flushed, even it was empty.
Now it's changed: we try to create the smallest number of table files by merging updates from multiple logs
83728. Verify
83729. we won't be needing this file no more
83730. Test variations of WriteImpl.
83731. Check each sequence is used once and only once.
83732. Sequence number should be return through input write batch.
83733. The sequence isn't consumed by someone else.

83747. 2 ssts, 1 manifest
83748. Make sure all background purges are executed
83749. 1 sst after iterator deletion
83750. 3 sst after compaction with live iterator
83751. ~DBImpl should wait until all BGWorkPurge are finished
83752. this time, we keep an iterator alive
83753. Take the last log file which is expected to be alive and try to delete it Should not succeed because live logs are not allowed to be deleted
83754. Call Flush to bring about a new working log file and add more keys Call Flush again to flush out memtable and move alive log to archived log and try to delete the archived log file
83755. Make sure no purges are executed foreground
83756. !ROCKSDB_LITE
83757. intermediate level files cannot be deleted.
83758. This test is to reproduce a bug that read invalid ReadOption in iterator cleanup function
83759. COntrolled setup. Levels 1 and 2 should both have 50K files. This is a little fragile as it depends on the current compaction heuristics.
83760. 5 sst files after 2 compactions with 2 live iterators
83761. always do full purge
83762. Used to test log files Used to test log files
83763. An empty job to guard all jobs are processed
83764. there should be only one (empty) log file because CreateTwoLevels() flushes the memtables to disk
83765. 1 sst after compaction
83766. We keep an iterator alive
83767. **comment:** ReadOptions is deleted, but iterator cleanup function should not be affected
 label: code-design
83768. Lowest level file deletion should succeed.
83769. file3.sst (110 => 124) .. overlap with file2.sst
83770. Write some keys through normal write path
83771. File dont overwrite any keys, No seqno needed
83772. we only use TestPutOperator in this test
83773. overlaps with memtable, so flush is triggered (thus file count increases by two at this step).
83774. namespace rocksdb
83775. copy file
83776. file2.sst (100 => 299)
83777. File overwrite some keys, a seqno will be assigned
83778. move file
83779. fadvise disabled
83780. Add file using file path
83781. We will need a seqno for the file regardless if the file overwrite keys in the DB or not because we have a snapshot
83782. A global seqno will be assigned anyway because of the snapshot
83783. fadvise enabled
83784. Current file size should be 0 after sst_file_writer init and before open a file.
83785. ROCKSDB_LITE
83786. overlaps with nothing, so places at bottom level and skips incrementing seqnum.
83787. overlaps with L0 file but not memtable, so flush is skipped
83788. prevent range deletions from being dropped due to becoming obsolete.
83789. This file have overlapping values with the existing data
83790. snapshot unneeded now that both range deletions are persisted
83791. No snapshot anymore, no need to assign a seqno
83792. sst_file_writer already finished, cannot add this value
83793. Current file size should be non-zero after success write.
83794. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
83795. file1.sst (0 => 99)
83796. range del [0, 50) in L0 file, [50, 100) in memtable
83797. check that we have change the old key
83798. Start ingesting and extrnal file in the background
83799. This file overlap with files in L4, we will ingest it in L3
83800. We intentionally add every file twice, and assert that it was added only once and the other add failed
83801. Verify data in files
83802. L3 L2 L1 L0
83803. L3 L2
83804. SST CF unknown
83805. Flush / Compact the DB
83806. file5.sst (200 => 299)
83807. Add file while holding a snapshot will fail
83808. file4.sst (30 => 39) This file values overlap with file1 values
83809. This thread will try to insert into the memtable but since we have 4 L0 files this thread will be blocked and hold the writer thread
83810. This file has overlapping values with the existing data
83811. Start a thread that will ingest a new file
83812. SST CF match
83813. files[0].sst (0 => 99) files[1].sst (100 => 199) ... file[8].sst (800 => 899)
83814. this time ingest should fail as the file doesn't fit to the bottom level
83815. Use DB::AddFile to insert range
83816. Make sure DelayWrite is called first
83817. file5.sst (400 => 499)
83818. Thread 0 -> Load {f0,f1} Thread 1 -> Load {f0,f1} Thread 2 -> Load {f2,f3} Thread 3 -> Load {f2,f3} Thread 4 -> Load {f4,f5} Thread 5 -> Load {f4,f5} ...
83819. Now let compaction start
83820. Generate the file containing the range
83821. We can add the file after releasing the snapshot
83822. Generate file names
83823. Can't ingest behind since allow_ingest_behind isn't set to true
83824. Write range [5 => 10] to L0
83825. CF was not dropped, ok to Ingest
83826. Flush and read from L0
83827. These 2 files dont overlap with each other
83828. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
83829. file3.sst (300 => 399)
83830. file #1 in L0

83831. This test reproduce a bug that can happen in some cases if the DB started purging obsolete files when we are adding an external sst file. This situation may result in deleting the file while it's being added.

83832. Universal picker should go at second from the bottom level

83833. This range overlap with data already exist in DB

83834. Current file size should be 0 after sst_file_writer init and before open a file.

83835. Use DB::Put to insert range (insert into memtable)

83836. Wait for IngestExternalFile() to start and aquire mutex

83837. This file dont overlap with anything in the DB, will go to L4

83838. Now we can add the file

83839. file #2 in L0

83840. Generate a file id if not provided

83841. This file does not overlap with any file or with the running compaction

83842. This file dont overlap with anything in the DB and fit in L4 as well

83843. Insert 100 -> 200 using IngestExternalFile

83844. Update true_data map to include the new inserted data

83845. Output of the compaction will go to L3

83846. Insert 30 -> 50 using AddFile

83847. SST CF dont match

83848. Add file using file path

83849. atomic counter of currently running bg threads

83850. Write num_files files in parallel

83851. Bulk load 10 files every file contain 1000 keys

83852. This file overlap with the memtable, so it will flush it and add it self to L0

83853. File 7 overlaps with file 4 (L3)

83854. Sort data if asked to do so

83855. file2.sst (100 => 199)

83856. Delete keys in range (200 => 299)

83857. While writing the MANIFEST start a thread that will ask for compaction

83858. cf1.sst

83859. Verify values of file5 in DB

83860. Current file size should be non-zero after success write.

83861. file1.sst (0 => 500)

83862. Generate files with these key ranges {14 -> 0} {24 -> 10} {34 -> 20} {44 -> 30} ..

83863. This file overlaps with the output of the compaction (going to L3) so the file will be added to L0 since L3 is the base level

83864. Insert 80 -> 130 using AddFile

83865. bottom level should be empty

83866. 25% of writes go through memtable

83867. Ingest into cf1

83868. We need to verify that no compactions can run while AddFile is ingesting the files into the levels it find suitable. So we will wait for 2 seconds to give a chance for compactions to run during this period, and then make sure that no compactions where able to run

83869. This file does not overlap with the current running compacting

83870. Make sure the values are correct before and after flush/compaction

83871. Insert 100 -> 200 into the memtable

83872. namespace rocksdb

83873. File 5 overlaps with file 2 (L3 / base level)

83874. file2.sst (100 => 299)

83875. Compacting the DB will remove the tombstones

83876. No need for flush, this file keys fit between the memtable keys

83877. File 1 will go to level L2 (since it overlap with file 0 in L3)

83878. Files dont overlap and dont overlap with DB key range

83879. Overwrite what we added using external files

83880. cf_unknown.sst

83881. list 1 has internal key range conflict

83882. check that we still can open the DB, as num_levels should be sanitized to 3

83883. Flush 4 files containing the same keys

83884. Hold AddFile from finishing writing the MANIFEST

83885. fit in L3 but will overlap with compaction so will be added to L2 but a compaction will trivially move it to L3 and break LSM consistency

83886. IROCKSDB_LITE

83887. `DBImpl::AddFile::Start` will wait until we be here

83888. We have 2 overlapping files in L0

83889. Wait for BackgroundCompaction() to be called

83890. Cannot add this key because it's not after last added key

83891. No Flush needed, but need a global seqno, Ingest in L0

83892. Overwrite values of keys divisible by 100

83893. default_cf.sst

83894. Verify the correctness of the data

83895. Read values from memtable

83896. Destruct SstFileWriter with a failing Finish

83897. file3.sst (195 => 199) This file values overlap with file2 values

83898. Delete keys in range (400 => 499)

83899. Insert 10 -> 40 using AddFile

83900. These 2nd and 3rd files overlap with each other

83901. sst_file_writer already finished, cannot add this value

83902. Current file size should be non-zero after success finish.

83903. file1.sst (0 => 99)

83904. This list of files have key ranges are overlapping with each other

83905. sometimes we use copy, sometimes link .. the result should be the same

83906. Insert 0 -> 20 using AddFile

83907. Add files using file path list

83908. We deleted range (200 => 299) but cannot add file5 because of the range tombstones

83909. This file will flush the memtable

83910. Make sure values are correct before and after flush/compaction

83911. No Flush needed, No global seqno needed, Ingest in L1

83912. Wait for max 5 seconds, if we did not finish all bg threads then we hit the deadlock bug

83913. Wait for AddFile to start picking levels and writing MANIFEST

83914. This file overlaps with file 0 (L3), file 1 (L2) and the output of compaction going to L1

83915. Ingest into cf2

83916. Cannot ingest a file into a dropped CF

83917. This file list has overlapping values with the existing data
83918. Insert the generated file
83919. Add file will fail when holding snapshot and use the default skip_snapshot_check to false
83920. Insert keys using normal path and take a snapshot
83921. No need for flush
83922. Bulk load num_files files in parallel
83923. Key range of file5 (400 => 499) dont overlap with any keys in DB
83924. File 6 overlaps with file 2 (L3 / base level) and file 5 (L0)
83925. Destuct SstFileWriter without calling Finish()
83926. Overwrite values of keys divisible by 5
83927. Ingest into default cf
83928. Overwrite all keys using IngestExternalFile
83929. Cannot create an empty sst file
83930. file3.sst (195 => 299) This file values overlap with file2 values
83931. File 0 will go to last level (L3)
83932. Add file will success when set skip_snapshot_check to true even db holding snapshot
83933. For 20% of ranges we use DB::Put, for 80% we use DB::AddFile
83934. We deleted range (400 => 499) but cannot add file5 because of the range tombstones
83935. Hold compaction from finishing
83936. These 2 files dont overlap with each other but overlap with keys in DB
83937. Return the current option configuration.
83938. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. 84005. Drop all payload as well as a header byte
84006. Remove the LAST block, including header.
84007. Write records that span two blocks
84008. Return a skewed potentially long string
84009. If an error occurs during Read() in UnmarkEOF(), the records contained in the buffer should be returned on subsequent calls of ReadRecord() until no more full records are left, whereafter ReadRecord() should return false to indicate that it cannot read any further.
84010. test is only valid for recycled logs
84011. checksum
84012. Returns OK iff recorded error message contains "msg"
84013. initial_offset
84014. Two sizable records in first block
84015. Construct a string of the specified length made out of the supplied partial string.
84016. Compute crc of type/len/data
84017. Make a trailer that is exactly the same length as an empty record.
84018. Span three blocks
84019. namespace log namespace rocksdb
84020. Truncated last record is ignored, not treated as an error
84021. Type is stored in header[6]
84022. Consider two fragmented records: first(R1) last(R1) first(R2) last(R2) where the middle two fragments disappear. We do not want first(R1),last(R2) to get joined and returned as a valid record.
84023. Tests of all the error paths in log_reader.cc follow:
84024. Cause a bad record length in the LAST block.
84025. Wipe the middle block
84026. Construct a string from a number
84027. Record metadata for testing initial offset functionality
84028. By using scratch we ensure that caller has control over the lifetime of result.data()
84029. Make sure reads at eof work
84030. compact database
84031. universal compaction
84032. create first key range
84033. close database
84034. create second key range
84035. Get rid of any state from an old run.
84036. level compaction
84037. delete second key range
84038. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory). Test for issue 178: a manual compaction causes deleted data to reappear.
84039. commenting out the line below causes the example to work correctly
84040. Open database. Disable compression since it affects the creation of layers and the code below is trying to test against a very specific scenario.
84041. count the keys
84042. anonymous namespace
84043. Create a mock VersionSet
84044. Add a third memtable to push the first memtable out of the history
84045. Create an empty MemTableList and validate basic functions.
84046. Create a test db if not yet created
84047. Attempt to 'flush' to clear request for flush
84048. namespace rocksdb
84049. Verify keys are no longer in MemTableList
84050. Note: now to_flush contains tables[0,1,2,4]. to_flush2 contains tables[3]. Current implementation will only commit memtables in the order they were created. So InstallMemtableFlushResults will install the first 3 tables in to_flush and stop when it encounters a table not yet flushed.
84051. Calls MemTableList::InstallMemtableFlushResults() and sets up all structures needed to call this function.
84052. **comment:** nothing in progress of being flushed
 label: requirement
84053. Request a flush again
84054. column_family_id
84055. Create some MemTables
84056. Add another table
84057. No flush pending since the list is empty.
84058. Create a mock Logger
84059. Request a flush even though there is nothing to flush
84060. Request a flush again. Should be nothing to flush
84061. Verify that key2 from the first memtable is no longer in the history
84062. Verify that the second memtable's keys are in the history
84063. This will actually install 2 tables. The 1 we told it to flush, and also tables[4] which has been waiting for tables[3] to commit.
84064. Create a MemTable
84065. Flush second memtable
84066. Verify keys are present in history
84067. Should pick 4 of 5 since 1 table has been picked in to_flush2
84068. We now have the minimum to flush regardless of whether FlushRequested()
84069. **comment:** Even though we have less than the minimum to flush, a flush is pending since we had previously requested a flush and never called PickMemtablesToFlush() to clear the flush.
 label: code-design
84070. Create MemTableList
84071. Pick tables to flush

84072. Add another tables
84073. Fetch the newly written keys
84074. Flush the 4 memtables that were picked in to_flush
84075. Add 2 tables
84076. We now have the minimum to flush regardless of whether FlushRequested() was called.
84077. Add second memtable to list
84078. Create dummy mutex.
84079. Write some keys to this memtable.
84080. Add memtable to list
84081. Nothing to flush
84082. MemTable found out that this key is *not* found (at this sequence#)
84083. Flush the 1 memtable that was picked in to_flush2
84084. Revert flush
84085. **comment:** Cleanup
 label: code-design
84086. Rollback first pick of tables

84400. verify that preallocated blocks were deallocated on file close Because the FS might give us more blocks, we add a full page to the size and expect the number of blocks to be less or equal to that.

84401. Write an entire preallocation block, make sure we increased by two.

84402. !defined(ROCKSDB_LITE) && !defined(OS_WIN)

84403. Remove it with a different tag

84404. Wake up task 0, 3 and 4. Task 5, 6, 7 running.

84405. 48 bytes for extra information + bytes allocated

84406. Data structures to signal tasks to run.

84407. Wait until the thread pools are empty.

84408. namespace

84409. Pointer to shared slot Order# for the execution of this callback

84410. Hold jobs to schedule;

84411. Set number of thread to 1 first.

84412. !defined(ROCKSDB_LITE)

84413. Change number of threads a couple of times while there is no sufficient tasks.

84414. No writes should mean no preallocation

84415. Wake up thread 8

84416. ROCKSDB_FALLOCATE_PRESENT

84417. Wake up thread 9.

84418. Enqueue thread 8 and 9. Task 5 running; one of 8, 9 might be running.

84419. **comment:** Determine whether we can use the FS_IOC_GETVERSION ioctl on a file in directory DIR. Create a temporary file therein, try to apply the ioctl (save that result), cleanup and return the result. Return true if it is supported, and false if anything fails. Note that this function "knows" that dir has just been created and is empty, so we create a simply-named test file: "f".
label: code-design

84420. Shrink back to 1 thread. Still task 0, 1 running, 2 waiting

84421. Remove it from the queue with the right tag

84422. not TRAVIS OS_LINUX || OS_WIN

84423. mkdtemp failed: diagnose it, but don't give up.

84424. Delete the file

84425. namespace rocksdb

84426. Write a page worth of 'a'

84427. Diagnose ioctl-related failure only if this is the directory specified via that envvar.

84428. Returns true if any of the strings in ss are the prefix of another string.

84429. Trigger jobs to run.

84430. Schedule in different order than start time

84431. IROCKSDB_LITE

84432. Travis doesn't support fallocate or getting unique ID from files for whatever reason.

84433. When we have n == -1 there is not a terminating zero expected

84434. verify that blocks are preallocated Note here that we don't check the exact number of blocks preallocated -- we only require that number of allocated blocks is at least what we expect. It looks like some FS give us more blocks than we asked for. That's fine. It might be worth investigating further.

84435. Write five more blocks at once, ensure we're where we need to be.

84436. Only works in linux and WIN platforms

84437. wait for all jobs to finish

84438. Test that the two ways to get children file attributes (in bulk or individually) behave consistently.

84439. Unblock background thread

84440. Generate random data

84441. Random Read

84442. Write to mirror string

84443. Increase to 2 threads. Task 0, 1 running; 2 waiting

84444. Pick random offset for read

84445. Wake up threads 7. Task 5 running

84446. Schedule another task

84447. make sure we don't have more than pool_size_jobs running.

84448. Shrink back to 1 thread. Still task 5, 6, 7 running

84449. Check whether a bunch of concurrently existing files have unique IDs.

84450. Check that after file is deleted we don't get same ID again in a new file.

84451. Pick random offset for write

84452. Block the low priority queue

84453. Wait a short while for the jobs to be dispatched.

84454. allocate 100 MB
84455. Get Unique ID
84456. Reopen the file every 500 iters
84457. The filesystem containing the file does not support fallocate
84458. Verify the above
84459. Check IDs are the same.
84460. "[DEBUG]"
84461. Get Unique ID again
84462. schedule same number of jobs in each pool
84463. Wake up task 6. Task 5, 7 running
84464. Close file and reopen it
84465. close the file, should deallocate the blocks
84466. Increase to 4 threads. Task 5, 8, 9 running.
84467. Collect and check whether the IDs are unique.
84468. The file now has 1 sector worth of a followed by a page worth of b

84767. Advance to next key in the valid key space

84768. Our test skip list stores 8-byte unsigned integers

84769. Seek to middle

84770. Backward iteration test

84771. Simple iterator tests

84772. namespace rocksdb

84773. **comment:** Simple test that does single-threaded testing of the ConcurrentTest scaffolding.
label: test

84774. Remember the initial committed state of the skiplist.

84775. Seek to end

84776. Compare against model iterator

84777. InlineSkipList is not protected by mu_. We just use a single writer thread to modify it.

84778. Note that generation 0 is never inserted, so it is ok if <*,0,*> is missing.

84779. Iterate over the list, make sure keys appears in order and no extra keys exist.

84780. REQUIRES: No concurrent calls to WriteStep or ConcurrentWriteStep

84781. Validate the list is well-formed.

84782. Seek to beginning

84783. REQUIRES: No concurrent calls for the same k

84784. Per-key generation

84785. Verify that everything in [pos,current) was not present in initial_state.

84786. Current state of the test

84787. We sometimes pass K to seek to the end of the skiplist

84788. **comment:** We want to make sure that with a single writer and multiple concurrent readers (with no synchronization other than when a reader's iterator is created), the reader always observes all the data that was present in the skip list when the iterator was constructor. Because insertions are happening concurrently, we may also observe new values that were inserted since the iterator was constructed, but we should never miss any values that were present at iterator construction time. We generate multi-part keys: <key,gen,hash> where: key is in range [0..K-1] gen is a generation number for key hash is hash(key,gen) The insertion code picks a random key, sets gen to be 1 + the last generation number inserted for that key, and sets hash to Hash(key,gen). At the beginning of a read, we snapshot the last inserted generation number for each key. We then iterate, including random calls to Next() and Seek(). For every key we encounter, we check that it is either expected given the initial snapshot or has been concurrently added since the iterator started.

84847. GFLAGS
84848. Need to update the option string if a new option is added.
84849. This option is not setable:
84850. **comment:** It based on the behavior of compiler that padding bytes are not changed when copying the struct. It's prone to failure when compiler behavior changes. We verify there is unset bytes to detect the case.
label: code-design
84851. Following options are not settable through GetColumnFamilyOptionsFromString():
84852. !__clang__ OS_LINUX || OS_WIN !ROCKSDB_LITE
84853. In this test, we catch a new option of BlockBasedTableOptions that is not settable through GetBlockBasedTableOptionsFromString(). We count padding bytes of the option struct, and assert it to be the same as unset bytes of an option struct initialized by GetBlockBasedTableOptionsFromString().
84854. Construct the base option passed into GetBlockBasedTableOptionsFromString().
84855. If the test fails, likely a new option is added to BlockBasedTableOptions but it cannot be set through GetBlockBasedTableOptionsFromString(), or the test is not updated accordingly. After adding an option, we need to make sure it is settable by GetBlockBasedTableOptionsFromString() and add the option to the input string passed to the GetBlockBasedTableOptionsFromString() in this test. If it is a complicated type, you also need to add the field to kBbtoBlacklist, and maybe add customized verification for it.
84856. Verify options are settable from options strings. We take the approach that depends on compiler behavior that copy constructor won't touch implicit padding bytes, so that the test is fragile. As a result, we only run the tests to verify new fields in options are settable through string on limited platforms as it depends on behavior of compilers.
84857. options in the blacklist need to appear in the same order as in ColumnFamilyOptions.
84858. If the test fails, likely a new option is added to ColumnFamilyOptions but it cannot be set through GetColumnFamilyOptionsFromString(), or the test is not updated accordingly. After adding an option, we need to make sure it is settable by GetColumnFamilyOptionsFromString() and add the option to the input string passed to GetColumnFamilyOptionsFromString() in this test. If it is a complicated type, you also need to add the field to kColumnFamilyOptionsBlacklist, and maybe add customized verification for it.
84859. Count padding bytes by setting all bytes in the memory to a special char, copy a well constructed struct to this memory and see how many special bytes left.

85172. DummyPropertiesCollector used to test BlockBasedTableProperties
85173. version == 2
85174. Helper function to get the contents of the table InternalIterator
85175. prefetch
85176. data, index and filter block
85177. bloom_filter_type = 0 -- block-based filter bloom_filter_type = 0 -- full filter

85178. invalid values for block_restart_interval (<1) are silently set to 1
85179. key_range=
85180. Hash search index with hash_index_allow_collision
85181. find existing keys
85182. At first, no block will be accessed.
85183. This test include all the basic checks except those for index size and block size, which will be conducted in separated unit tests.
85184. preloading filter/index blocks is enabled.
85185. !ROCKSDB_LITE
85186. Plain table is not supported in ROCKSDB_LITE
85187. filter is already in memory and it figures out that the key doesn't exist
85188. k04 and k05 will be in two consecutive blocks, the index is an arbitrary slice between k04 and k05, either before or after k04
85189. Trigger compaction.
85190. In the second round, turn whole_key_filtering off and expect rocksdb still works.
85191. seek the first element in the block
85192. xxhash block based
85193. prefixes that exist
85194. ASSERT_TRUE(regular_iter->Valid());
85195. A wrapper around LRICache that also keeps track of data blocks (in contrast with the objects) in the cache. The class is very simple and can be used only for trivial tests.
85196. invalid values for block_size_deviation (<0 or >100) are silently set to 0
85197. Check that when we reopen a table we don't lose access to blocks already in the cache. This test checks whether the Table actually makes use of the unique ID from the file.
85198. big enough so we don't ever lose cached values.
85199. Hash search index with filter policy
85200. Due to the difficulties of the intersection between statistics, this test only tests the case when "index block is put to block cache"
85201. Cache miss, Bytes read from cache should not change
85202. Release pinnable slice resources
85203. just the data block
85204. Something small to force merging
85205. Hash search index
85206. keys_in_cache=
85207. Returns nullptr if not running against a DB
85208. Verify data size.
85209. PlainTable expects internal key structure
85210. Replace the deleter with our own so that we keep track of data blocks erased from the cache
85211. last key
85212. For second iteration, delete the table reader object and verify the iterator can still access its metablock's range tombstones.
85213. data block miss
85214. odd
85215. index will be added to block cache. index block miss
85216. If the item was marked for being data block, decrease its usage from the total data block usage of the cache
85217. Return something larger than an existing key
85218. Overridden in DBConstructor
85219. Make sure, by default, index/filter blocks were pre-loaded (meaning we won't use block cache to store them).
85220. if (!BZip2_Supported()) { fprintf(stderr, "skipping bzip2 compression tests\n"); } else { compression_state.push_back(kBZip2Compression); }
85221. A simple tool that takes the snapshot of block cache statistics.
85222. Edge cases
85223. Attempt to return something smaller than an existing key
85224. This is called by the application right after inserting a data block
85225. -- PART 2: Open with very small block cache In this test, no block will ever get hit since the block cache is too small to fit even one entry.
85226. Test point lookup
85227. Finish constructing the data structure with all the keys that have been added so far. Returns the keys in sorted order in "*keys" and stores the key/value pairs in "**kvmap"
85228. The only usage must be for marked data blocks
85229. **comment:** we need to use random keys since the pure human readable texts may be well compressed, resulting in significant change of index block size.
 label: code-design
85230. with full-filter, we read filter first and then we stop
85231. No prefix extractor
85232. **comment:** Wrap around to invalid value
 label: code-design
85233. We must have created enough data to force merging
85234. find the lower bound of the prefix
85235. -- PART 3: Open table with bloom filter enabled but not in SST file
85236. BlockBasedTableTest::PrefetchTest
85237. upconvert legacy plain table
85238. Doing a read to make index/filter loaded into the cache
85239. Helper function to update the value of the global seqno in the file
85240. regular_iter->Seek(prefix);
85241. Open the table
85242. Plain table doesn't use restart index or compression.
85243. index block miss data block miss
85244. keys with prefix length 3, make sure the key/value is big enough to fill one block
85245. It's very hard to figure out the index block size of a block accurately. To make sure we get the index size, we just make sure as key number grows, the filter block size also grows.
85246. Compression type == that set:
85247. To tickle the PrefixMayMatch bug it is important that the user-key is a single byte so that the index key exactly matches the user-key.
85248. Only index block will be accessed
85249. Then call the original deleter
85250. index block hit
85251. Update global sequence number to 10
85252. Return an existing key
85253. Helper class for tests to unify the interface between BlockBuilder/TableBuilder and Block/Table.
85254. Only add compression if it is supported
85255. Open table with filter policy
85256. There must be some pinned data since PinnableSlice has not released them yet
85257. SeekToFirst() accesses data block. With similar reason, we expect data block's cache miss.
85258. -- Table construction
85259. **comment:** TODO(kailiu) DoCompressionTest() doesn't work with BZip2.

label: requirement

85260. Simple

85261. Seek to non-existing prefixes should yield either invalid, or a key with prefix greater than the target.

85262. Reads and returns the string environment variable corresponding to the given flag; if it's not set, returns default_value.

85263. Deletes the test object.

85264. iteration

85265. class Test

85266. Class UnitTestOptions. This class contains functions for processing options the user specifies when running the tests. It has only static members. In most cases, the user can specify an option using either an environment variable or a command line flag. E.g. you can set the test filter using either GTEST_FILTER or --gtest_filter. If both the variable and the flag are present, the latter overrides the former.

85267. **comment:** MSVC 8 deprecates _ftime64(), so we want to suppress warning 4996 (deprecated function) there. TODO(kenton@google.com): Use GetTickCount()? Or use SystemTimeToFileTime()

label: code-design

85268. **comment:** When compiled with MSVC 7.1 in optimized mode, destroying the UnitTest object upon exiting the program messes up the exit code, causing successful tests to appear failed. We have to use a different implementation in this case to bypass the compiler bug. This implementation makes the compiler happy, at the cost of leaking the UnitTest object.

label: code-design

85269. Compares two wide C strings, ignoring case. Returns true iff they have the same content. Unlike wcscasecmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NUL wide C string, including the empty string. NB: The implementations on different platforms slightly differ. On Windows, this method uses _wcsicmp which compares according to LC_CTYPE environment variable. On GNU platform this method uses wcscasecmp which compares according to LC_CTYPE category of the current locale. On Mac OS X, it uses towlower, which also uses LC_CTYPE category of the current locale.

85270. The following two functions only make sense if the system uses UTF-16 for wide string encoding. All supported systems with 16 bit wchar_t (Windows, Cygwin, Symbian OS) do use UTF-16.

85271. Allows user supplied key value pairs to be recorded for later output.

85272. **comment:** However, we want to clean up as much as possible. Hence we will always call TearDown(), even if SetUp() or the test body has failed.

label: code-design

85273. **comment:** Converting via modulus introduces a bit of downward bias, but it's simple, and a linear congruential generator isn't too good to begin with.

label: code-design

85274. The time of the test program start, in ms from the start of the UNIX epoch.

85275. Creates a client socket and connects to the server.

85276. **comment:** The default death test style.

label: test

85277. A working implementation of the OsStackTraceGetterInterface interface.

85278. When we fork the process below, the log file buffers are copied, but the file descriptors are shared. We flush all log files here so that closing the file descriptors in the child process doesn't throw off the synchronization between descriptors and buffers in the parent process. This is as close to the fork as possible to avoid a race condition in case there are multiple threads running before the death test, and another thread writes to the log file.

85279. Prints a ::string object.

85280. Clean up the ThreadLocalValues data structure while holding the lock, but defer the destruction of the ThreadLocalValueHolderBases.

85281. **comment:** Clears the results of all tests, except the ad hoc tests.

label: test

85282. **comment:** For more convenience, we print c's code again in hexadecimal, unless c was already printed in the form '\x##' or the code is in [1, 9].

label: code-design

85283. Continue only if the next hunk is very close.

85284. Our random number generator.

85285. GTEST_HAS_TYPED_TEST_P

85286. Formats a source file path and a line number as they would appear in an error message from the compiler used to compile this code.

85287. Formats the count of tests.

85288. Add a spacer if no FAILURE banner is displayed.

85289. Sets the default_result_printer attribute to the provided listener. The listener is also added to the listener list and previous default_result_printer is removed from it and deleted. The listener can also be NULL in which case it will not be added to the list. Does nothing if the previous and the current listener objects are the same.

85290. Sets the TestCase object for the test that's currently running.

85291. **comment:** TODO(vladl@google.com): Replace the following check with a compile-time assertion when available.

label: code-design

85292. Prints the given array of characters to the ostream. CharType must be either char or wchar_t. The array starts at begin, the length is len, it may include '\0' characters and may not be NUL-terminated.

85293. **comment:** We create the exception message on the heap because VC++ prohibits creation of objects with destructors on stack in functions using __try (see error C2712).

label: code-design

85294. Prints a string containing code-encoded text. The following escape sequences can be used in the string to control the text color: @@ prints a single '@' character. @R changes the color to red. @G changes the color to green. @Y changes the color to yellow. @D changes to the default terminal text color.

TODO(wan@google.com): Write tests for this once we add stdout capturing to Google Test.

85295. Don't strip off trailing separator if path is a root directory on Windows (like "C:\\").

85296. Prints a (const) wchar_t array of 'len' elements, starting at address 'begin'.

85297. Returns true iff Google Test should use colors in the output.

85298. **comment:** Helper class that holds the state for one hunk and prints it out to the stream. It reorders adds/removes when possible to group all removes before all adds. It also adds the hunk header before printing into the stream.

label: code-design

85299. Returns the message describing the last system error, regardless of the platform.

85300. Runs the test only if the test object was created and its constructor didn't generate a fatal failure.

85301. It is an error to pass this method a listener that is already in the list.

85302. namespace testing Copyright 2008, Google Inc. All rights reserved. Author: mheule@google.com (Markus Heule) The Google C++ Testing Framework (Google Test)

85303. **comment:** How many times to repeat the tests? We don't want to repeat them when we are inside the subprocess of a death test.

label: test

85304. Constructs and returns the message for an equality assertion (e.g. ASSERT_EQ, EXPECT_STREQ, etc) failure. The first four parameters are the expressions used in the assertion and their values, as strings. For example, for ASSERT_EQ(foo, bar) where foo is 5 and bar is 6, we have: expected_expression: "foo" actual_expression: "bar" expected_value: "5" actual_value: "6" The ignoring_case parameter is true iff the assertion is a *_STRCASEEQ*. When it's true, the string "(ignoring case)" will be inserted into the message.

85305. **comment:** Assume other platforms have `gettimeofday()`. TODO(kenton@google.com): Use autoconf to detect availability of `gettimeofday()`.
label: requirement
85306. Information about a Google Test trace point.
85307. `GTEST_HAS_CLONE`
85308. Functions for processing the `gtest_filter` flag.
85309. Prints a (const) char array of 'len' elements, starting at address 'begin'.
85310. We are on Windows proper.
85311. Given the total number of shards, the shard index, and the test id, returns true iff the test should be run on this shard. The test id is some arbitrary but unique non-negative integer assigned to each test method. Assumes that $0 \leq \text{shard_index} < \text{total_shards}$.
85312. Ensures that this function does not execute more than once.
85313. Shuffles the death test cases.
85314. If `*pstr` starts with the given prefix, modifies `*pstr` to be right past the prefix and returns true; otherwise leaves `*pstr` unchanged and returns false. None of `pstr`, `*pstr`, and `prefix` can be NULL.
85315. Waits for the child process to exit if it haven't already. This returns immediately if the child has already exited, regardless of whether previous calls to `WaitForMultipleObjects` synchronized on this handle or not.
85316. This helper class can be used to mock out Google Test failure reporting so that we can test Google Test or code that builds on Google Test. An object of this class appends a `TestPartResult` object to the `TestPartResultArray` object given in the constructor whenever a Google Test failure is reported. It can either intercept only failures that are generated in the same thread that created this object or it can intercept all generated failures. The scope of this mock object can be controlled with the second argument to the two arguments constructor.
85317. Creates a Unicode code point from UTF16 surrogate pair.
85318. The vector of `TestCases` in their original order. It owns the elements in the vector.
85319. Destructor of `TestCase`.
85320. class `PrettyUnitTestResultPrinter`
85321. `max_depth`
85322. Gets the value of the flag as a string.
85323. **comment:** TODO(kenton@google.com): Shouldn't this just use `GetSystemTimeAsFileTime()`?
label: code-design
85324. Creates a new `TestInfo` object and registers it with Google Test; returns the created object. Arguments: `test_case_name`: name of the test case name; `name` of the test type `_param`: the name of the test's type parameter, or NULL if this is not a typed or a type-parameterized test. `value_param`: text representation of the test's value parameter, or NULL if this is not a value-parameterized test. `fixture_class_id`: ID of the test fixture class `set_up_tc`: pointer to the function that sets up the test case `tear_down_tc`: pointer to the function that tears down the test case factory: pointer to the factory that creates a test object. The newly created `TestInfo` instance will assume ownership of the factory object.
85325. Creates an ANSI string from the given wide string, allocating memory using `new`. The caller is responsible for deleting the return value using `delete[]`. Returns the ANSI string, or NULL if the input is NULL.
85326. The text used in failure messages to indicate the start of the stack trace.
85327. Checks if `str` contains '`-`', '`&`', '`%`' or '`\n`' characters. If yes, replaces them by "%xx" where xx is their hexadecimal value. For example, replaces "`=`" with "%3D". This algorithm is O(`strlen(str)`) in both time and space -- important as the input `str` may contain an arbitrarily long test failure message and stack trace.
85328. `getcwd` will likely fail in NaCl due to the sandbox, so return something reasonable. The user may have provided a shim implementation for `getcwd`, however, so fallback only when failure is detected.
85329. Returns true iff regex matches a prefix of `str`. `regex` must be a valid simple regular expression and not start with "`^`", or the result is undefined.
85330. We also need to decrement the iterator as we just removed an element.
85331. **comment:** Returns true iff regex matches any substring of `str`. `regex` must be a valid simple regular expression, or the result is undefined. The algorithm is recursive, but the recursion depth doesn't exceed the regex length, so we won't need to worry about running out of stack space normally. In rare cases the time complexity can be exponential with respect to the regex length + the string length, but usually it's must faster (often close to linear).
label: code-design
85332. The helper function for `{ASSERT|EXPECT}_EQ` with int or enum arguments.
85333. Use the `getaddrinfo()` to get a linked list of IP addresses for the given host name.
85334. Makes sure `full_pattern_` starts with '`\n`'.
85335. Makes sure `full_pattern_` ends with '`$`'.
85336. Has `strtol()` consumed all characters in the string?
85337. Returns true iff the test name of `test_info` matches `name_`.
85338. `WindowsDeathTest` uses an anonymous pipe to communicate results of a death test.
85339. Getters for the per-thread Google Test trace stack.
85340. In order to support thread-safe death tests, we need to remember the original working directory when the test program was first invoked. We cannot do this in `RUN_ALL_TESTS()`, as the user may have changed the current directory before calling `RUN_ALL_TESTS()`. Therefore we capture the current directory in `AddTestInfo()`, which is called to register a TEST or TEST_F before `main()` is reached.
85341. Clears the results of ad-hoc test assertions.
85342. Returns true iff `str` ends with the given suffix, ignoring case. Any string is considered to end with an empty suffix.
85343. Formats a countable noun. Depending on its quantity, either the singular form or the plural form is used. e.g. `FormatCountableNoun(1, "formula", "formuli")` returns "1 formula". `FormatCountableNoun(5, "book", "books")` returns "5 books".
85344. Mutex for linked pointers.
85345. Helper template for implementing `FloatLE()` and `DoubleLE()`.
85346. End `PrettyUnitTestResultPrinter`
85347. or if `val1` is almost equal to `val2`.
85348. **comment:** Returns an XML-escaped copy of the input string `str`. If `is_attribute` is true, the text is meant to appear as an attribute value, and normalizable whitespace is preserved by replacing it with character references. Invalid XML characters in `str`, if any, are stripped from the output. It is expected that most, if not all, of the text processed by this module will consist of ordinary English text. If this module is ever modified to produce version 1.1 XML output, most invalid characters can be retained using character references. TODO(wan): It might be nice to have a minimally invasive, human-readable escaping scheme for invalid characters, rather than dropping them.
label: code-design
85349. Gets the random seed used at the start of the current test iteration.
85350. class `UnitTest`
85351. Adds a `TestPartResult` to the current `TestResult` object. All Google Test assertion macros (e.g. `ASSERT_TRUE`, `EXPECT_EQ`, etc) eventually call this to report their results. The user code should use the assertion macros instead of calling this directly.
85352. `str` and `flag` must not be NULL.
85353. `ParseInternalRunDeathTestFlag()` has performed all the necessary processing.
85354. A concrete death test class that forks, then immediately runs the test in the child process.
85355. Symbian OpenC has `PATH_MAX` in `sys/syslimits.h`
85356. Returns true iff the test case failed.
85357. Parses the command line for Google Test flags, without initializing other parts of Google Test.
85358. **comment:** A struct that encompasses the arguments to the child process of a threadsafe-style death test process.
label: code-design
85359. Gets the number of all tests.
85360. `IsSubstring()` and `IsNotSubstring()` check whether `needle` is a substring of `haystack` (NULL is considered a substring of itself only), and return an appropriate error message when they fail.
85361. `!GTEST_OS_QNX`
85362. Google Test - The Google C++ Testing Framework This file implements a universal value printer that can print a value of any type T: void `::testing::internal::UniversalPrinter<T>::Print(value, ostream_ptr);` It uses the `<<` operator when possible, and prints the bytes in the object otherwise. A user can

override its behavior for a class type Foo by defining either operator<<(::std::ostream&, const Foo&) or void PrintTo(const Foo&, ::std::ostream*) in the namespace that defines Foo.

85363. Restores the current working directory.

85364. Converts a wide string to a narrow string in UTF-8 encoding. The wide string is assumed to have the following encoding: UTF-16 if sizeof(wchar_t) == 2 (on Windows, Cygwin, Symbian OS) UTF-32 if sizeof(wchar_t) == 4 (on Linux) Parameter str points to a null-terminated wide string. Parameter num_chars may additionally limit the number of wchar_t characters processed. -1 is used when the entire string should be processed. If the string contains code points that are not valid Unicode code points (i.e. outside of Unicode range U+0 to U+10FFFF) they will be output as '(Invalid Unicode 0xXXXXXXXXX)'. If the string is in UTF16 encoding and contains invalid UTF-16 surrogate pairs, values in those pairs will be encoded as individual Unicode characters from Basic Normal Plane.

85365. A function for deleting an object. Handy for being used as a functor.

85366. Pushes a trace defined by SCOPED_TRACE() on to the per-thread Google Test trace stack.

85367. Gets the number of failed tests in this test case.

85368. Returns a pathname for a file that does not currently exist. The pathname will be directory/base_name.extension or directory/base_name_<number>.extension if directory/base_name.extension already exists. The number will be incremented until a pathname is found that does not already exist. Examples: 'dir/foo_test.xml' or 'dir/foo_test_1.xml'. There could be a race condition if two or more processes are calling this function at the same time -- they could both pick the same filename.

85369. Death test constructor. Increments the running death test count for the current test.

85370. True iff at least one test has failed.

85371. The output file.

85372. Returns a copy of the FilePath with the directory part removed. Example: FilePath("path/to/file").RemoveDirectoryName() returns FilePath("file"). If there is no directory part ("just_a_file"), it returns the FilePath unmodified. If there is no file part ("just_a_dir") it returns an empty FilePath (""). On Windows platform, '\' is the path separator, otherwise it is '/'.

85373. Dynamic mutexes are initialized in the constructor.

85374. The following methods override what's in the TestEventListener class.

85375. Runs the given method and catches and reports C++ and/or SEH-style exceptions, if they are supported; returns the 0-value for type Result in case of an SEH exception.

85376. An error is OK if the directory exists.

85377. The value of GTEST_FLAG(catch_exceptions) at the moment RunAllTests() starts.

85378. Reads the entire content of a file as an std::string.

85379. NOTE: The user code can affect the way in which Google Test handles exceptions by setting GTEST_FLAG(catch_exceptions), but only before RUN_ALL_TESTS() starts. It is technically possible to check the flag after the exception is caught and either report or re-throw the exception based on the flag's value: try { // Perform the test method. } catch (...) { if (GTEST_FLAG(catch_exceptions)) // Report the exception as failure. else throw; // Re-throws the original exception. } However, the purpose of this flag is to allow the program to drop into the debugger when the exception is thrown. On most platforms, once the control enters the catch block, the exception origin information is lost and the debugger will stop the program at the point of the re-throw in this function -- instead of at the point of the original throw statement in the code under test. For this reason, we perform the check early, sacrificing the ability to affect Google Test's exception handling in the method where the exception is thrown.

85380. End XmlUnitTestResultPrinter

85381. **comment:** If we are in the child process of a death test, don't create/delete the premature exit file, as doing so is unnecessary and will confuse the parent process. Otherwise, create/delete the file upon entering/leaving this function. If the program somehow exits before this function has a chance to return, the premature-exit file will be left undeleted, causing a test runner that understands the premature-exit-file protocol to report the test as having failed.

label: code-design

85382. Index of the last death test case registered. Initially -1.

85383. In the debug version, Visual Studio pops up a separate dialog offering a choice to debug the aborted program. We need to suppress this dialog or it will pop up for every EXPECT/ASSERT_DEATH statement executed. Google Test will notify the user of any unexpected failure via stderr. VC++ doesn't define _set_abort_behavior() prior to the version 8.0. Users of prior VC versions shall suffer the agony and pain of clicking through the countless debug dialogs. TODO(vlidl@google.com): find a way to suppress the abort dialog() in the debug mode when compiled with VC 7.1 or lower.

85384. The AssumeRole process for a fork-and-exec death test. It re-executes the main program from the beginning, setting the --gtest_filter and --gtest_internal_run_death_test flags to cause only the current death test to be re-run.

85385. class TestEventRepeater This class forwards events to other event listeners.

85386. Print failure message from the assertion (e.g. expected this and got that).

85387. We don't use sprintf or strncpy, as they trigger a warning when compiled with VC++ 8.0.

85388. Tells the unit test event listener that the tests have just finished.

85389. The parsed value overflows as an Int32.

85390. Parses a string for an Int32 flag, in the form of "--flag=value". On success, stores the value of the flag in *value, and returns true. On failure, returns false without changing *value.

85391. namespace posix GTEST_OS_WINDOWS_MOBILE

85392. When def_optional is true, it's OK to not have a "=value" part.

85393. Sets the test part result reporter for the current thread.

85394. NOLINT GTEST_OS_WINDOWS

85395. The environment variable name for the test shard status file.

85396. **comment:** Prints an XML representation of a TestInfo object. TODO(wan): There is also value in printing properties with the plain printer.

label: code-design

85397. Returns the current OS stack trace as an std::string. The maximum number of stack frames to be included is specified by the gtest_stack_trace_depth flag. The skip_count parameter specifies the number of top frames to be skipped, which doesn't count against the number of frames to be included. For example, if Foo() calls Bar(), which in turn calls CurrentOsStackTraceExceptTop(1), Foo() will be included in the trace but Bar() and CurrentOsStackTraceExceptTop() won't.

85398. This doesn't throw as all user code that can throw are wrapped into exception handling code.

85399. Yes. Shift the remainder of the argv list left by one. Note that argv has (*argc + 1) elements, the last one always being NULL. The following loop moves the trailing NULL element as well.

85400. RemoveFileName returns the directory path with the filename removed. Example: FilePath("path/to/file").RemoveFileName() returns "path/to/". If the FilePath is "a_file" or "/a_file", RemoveFileName returns FilePath("./") or, on Windows, FilePath("\\"). If the filepath does not have a file, like "just/a/dir/", it returns the FilePath unmodified. On Windows platform, '\' is the path separator, otherwise it is '/'.

85401. A valid random seed must be in [1, kMaxRandomSeed].

85402. class UnitTestImpl

85403. **comment:** Since most methods are very similar, use macros to reduce boilerplate. This defines a member that forwards the call to all listeners.

label: code-design

85404. Helper function for *_STREQ on wide strings.

85405. Returns the message describing the last system error in errno.

85406. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.

85407. Is the parsed value in the range of an Int32?
85408. Prints the given C string to the ostream.
85409. The list of reserved attributes used in the <testcase> element of XML output.
85410. A test case whose name matches this filter is considered a death test case and will be run before test cases whose name doesn't match this filter.
85411. **comment:** We cannot call numeric_limits::max() as it conflicts with the max() macro on Windows.
 label: code-design
85412. Windows CE doesn't define INVALID_FILE_ATTRIBUTES
85413. Prints a TestPartResult object.
85414. Converts the given epoch time in milliseconds to a date string in the ISO 8601 format, without the timezone information.
85415. Prints an XML summary of unit_test to output stream out.
85416. Initializes the event listener for streaming test results to a socket. Must not be called before InitGoogleTest.
85417. Returns the current time in milliseconds.
85418. Returns ParameterizedTestCaseRegistry object used to keep track of value-parameterized tests and instantiate and register them.
85419. Runs all tests in this UnitTest object, prints the result, and returns true if all tests are successful. If any exception is thrown during a test, this test is considered to be failed, but the rest of the tests will still be run.
85420. The newly initialized handle is accessible only in the parent process. To obtain one accessible within the child, we need to use DuplicateHandle.
85421. Adds a TestInfo to the unit test. Arguments: set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case test_info: the TestInfo object
85422. The parent process considers the death test to be a failure if it finds any data in our pipe. So, here we write a single flag byte to the pipe, then exit.
85423. The c'tor sets this object as the test part result reporter used by Google Test. The 'result' parameter specifies where to report the results. This reporter will only catch failures generated in the current thread. DEPRECATED
85424. Converts an array of wide chars to a narrow string using the UTF-8 encoding, and streams the result to the given Message object.
85425. Fired before each iteration of tests starts.
85426. Returns the current OS stack trace as an std::string. The maximum number of stack frames to be included is specified by the gtest_stack_trace_depth flag. The skip_count parameter specifies the number of top frames to be skipped, which doesn't count against the number of frames to be included. For example, if Foo() calls Bar(), which in turn calls GetCurrentOsStackTraceExceptTop(..., 1), Foo() will be included in the trace but Bar() and GetCurrentOsStackTraceExceptTop() won't.
85427. The current color.
85428. GTEST_HAS_GLOBAL_STRING
85429. _MSC_VER
85430. The decomposed components of the gtest_internal_run_death_test flag, parsed when RUN_ALL_TESTS is called.
85431. **comment:** MinGW has gettimeofday() but not _ftime64(). TODO(kenton@google.com): Use autoconf to detect availability of gettimeofday().
 TODO(kenton@google.com): There are other ways to get the time on Windows, like GetTickCount() or GetSystemTimeAsFileTime(). MinGW supports these. consider using them instead.
 label: code-design
85432. Increments the test part result count and remembers the result. This method is from the TestPartResultReporterInterface interface.
85433. Note that Google Test currently only reports elapsed time for each test iteration, not for the entire test program.
85434. May appear in a well-formed XML document?
85435. Possibly yields the rest of the thread's time slice to other threads.
85436. Prints a segment of bytes in the given object.
85437. Everything up to the dash
85438. Everything after the dash
85438. **comment:** Name of the temporary file holding the stderr output.
 label: code-design
85439. Info about the current test.
85440. Prints a wchar_t c as if it's part of a string literal, escaping it when necessary; returns how c was formatted.
85441. Appends a TestPartResult to the array.
85442. Some Linux distributions define PATH_MAX here. GTEST_OS_WINDOWS_MOBILE
85443. Notify the streaming server to stop.
85444. Google Test implements this protocol for catching that a test program exits before returning control to Google Test: 1. Upon start, Google Test creates a file whose absolute path is specified by the environment variable TEST_PREMATURE_EXIT_FILE. 2. When Google Test has finished its work, it deletes the file. This allows a test runner to set TEST_PREMATURE_EXIT_FILE before running a Google-Test-based test program and check the existence of the file at the end of the test execution to see if it has exited prematurely.
85445. This is called from a death test parent process to read a failure message from the death test child process and log it with the FATAL severity. On Windows, the message is read from a pipe handle. On other platforms, it is read from a file descriptor.
85446. Returns the name of the requested output file, or the default if none was explicitly specified.
85447. Generates a textual description of a given exit code, in the format specified by wait(2).
85448. Same as above, but you can choose the interception scope of this object.
85449. True if the death test child process has been successfully spawned.
85450. No need to calculate the full pattern when the regex is invalid.
85451. wchar_t is native
85452. A filter is a colon-separated list of patterns. It matches a test if any pattern in it matches the test.
85453. This code is unreachable but some compilers may not realize that.
85454. Restores the original stream.
85455. Converts a wide C string to an std::string using the UTF-8 encoding. NULL will be converted to "(null)".
85456. Deletes every Environment.
85457. Sets the OS stack trace getter. Does nothing if the input and the current OS stack trace getter are the same; otherwise, deletes the old getter and makes the input the current getter.
85458. Appends the user message if it's non-empty.
85459. Returns true if pathname describes something findable in the file-system, either a file, directory, or whatever.
85460. Restores the text color.
85461. Returns the current OS stack trace getter if it is not NULL; otherwise, creates an OsStackTraceGetter, makes it the current getter, and returns it.
85462. Gets the number of disabled tests.
85463. Parses 'str' for a 32-bit signed integer. If successful, writes the result to *value and returns true; otherwise leaves *value unchanged and returns false.
85464. **comment:** Helpers for printing colored strings to stdout. Note that on Windows, we cannot simply emit special characters and have the terminal change colors.
 This routine must actually emit the characters rather than return a string that would be colored when printed, as can be done on Linux.
 label: code-design
85465. The d'tor restores the values of all Google Test flags.
85466. Clears the object.
85467. iteration
85468. These constants are the same as are used in glibc's rand(3).
85469. Appends the TestPartResult object to the TestPartResultArray received in the constructor. This method is from the TestPartResultReporterInterface interface.
85470. **comment:** Shuffles the tests in this test case.
 label: test
85471. Implements the helper function for {ASSERT|EXPECT}_GE with int or enum arguments.
85472. !GTEST_OS_WINDOWS
85473. The exit status of the child process.
85474. Maximum stack alignment in bytes: For a downward-growing stack, this amount is subtracted from size of the stack space to get an address that is within the stack space and is aligned on all systems we care about. As far as I know there is no ABI with stack alignment greater than 64. We assume stack and stack_size already

have alignment of kMaxStackAlignment.

85475. Sets up the test fixture. A sub-class may override this.

85476. GTEST_IMPLEMENTATION_ is defined to 1 iff the current translation unit is part of Google Test's implementation; otherwise it's undefined.

85477. Dereference NULL through a volatile pointer to prevent the compiler from removing. We use this rather than abort() or __builtin_trap() for portability: Symbian doesn't implement abort() well, and some debuggers don't correctly trap abort().

85478. Matches a repeated regex atom followed by a valid simple regular expression. The regex atom is defined as c if escaped is false, or \c otherwise. repeat is the repetition meta character (?*, ?, or +). The behavior is undefined if str contains too many characters to be indexable by size_t, in which case the test will probably time out anyway. We are fine with this limitation as std::string has it too.

85479. AssertionResult constructors. Used in EXPECT_TRUE/FALSE(assertion_result).

85480. Make sure AddressSanitizer does not tamper with the stack here.

85481. **comment:** Constructs an empty Message. We allocate the stringstream separately because otherwise each use of ASSERT/EXPECT in a procedure adds over 200 bytes to the procedure's stack frame leading to huge stack frames in some cases; gcc does not reuse the stack space.
label: code-design

85482. **comment:** TODO(wan@google.com): fix the source file location in the assertion failures to match where the regex is used in user code.
label: code-design

85483. MSVC and C++ Builder define __int64 instead of the standard long long.

85484. Obtains the current directory and sets it to be closed in the child process.

85485. Assesses the success or failure of a death test, using both private members which have previously been set, and one argument: Private data members: outcome: An enumeration describing how the death test concluded: DIED, LIVED, THREW, or RETURNED. The death test fails in the latter three cases. status: The exit status of the child process. On *nix, it is in the format specified by wait(2). On Windows, this is the value supplied to the ExitProcess() API or a numeric code of the exception that terminated the program. regex: A regular expression object to be applied to the test's captured standard error output; the death test fails if it does not match. Argument: status_ok: true if exit_status is acceptable in the context of this particular death test, which fails if it is false Returns true iff all of the above conditions are met. Otherwise, the first failing condition, in the order given above, is the one that is reported. Also sets the last death test message string.

85486. YYYY-MM-DDThh:mm:ss

85487. Verifies that the given attribute belongs to the given element and streams the attribute as XML.

85488. Clears the results of all tests in this test case.

85489. Makes a failed assertion result.

85490. Used in ThreadLocal.

85491. **comment:** Returns the TestResult for the test that's currently running, or the TestResult for the ad hoc test if no test is running.
label: test

85492. Returns the current OS stack trace as an std::string. Parameters: max_depth - the maximum number of stack frames to be included in the trace. skip_count - the number of top frames to be skipped; doesn't count against max_depth.

85493. Returns true iff the test case passed.

85494. The returned handle will be kept in thread_map and closed by watcher_thread in WatcherThreadFunc.

85495. By default, we want there to be enough precision when printing a double to a Message.

85496. Non-special character. Matches itself.

85497. GTEST_HAS_STD_WSTRING

85498. Parses the command line for Google Test flags, without initializing other parts of Google Test. The type parameter CharType can be instantiated to either char or wchar_t.

85499. Returns the TestInfo object for the test that's currently running, or NULL if no test is running.

85500. class SocketWriter

85501. Gets the random number generator.

85502. The child has acquired the write end of the pipe or exited. We release the handle on our side and continue.

85503. **comment:** First, print c as a literal in the most readable form we can find.
label: code-design

85504. gtest_break_on_failure takes precedence over gtest_throw_on_failure. This allows a user to set the latter in the code (perhaps in order to use Google Test assertions with another testing framework) and specify the former on the command line for debugging.

85505. Iterate the edits until we found enough suffix for the hunk or the input is over.

85506. No. Let's create one.

85507. __clang_analyzer__

85508. A successful match can be anywhere in str.

85509. Skips to the first non-space char in str. Returns an empty string if str contains only whitespace characters.

85510. Returns the i-th test property. i can range from 0 to test_property_count() - 1. If i is not in that range, aborts the program.

85511. Implements the helper function for {ASSERT|EXPECT}_GT with int or enum arguments.

85512. The helper function for {ASSERT|EXPECT}_STRCASENE.

85513. Ensure that Google Test output is printed before, e.g., heapchecker output.

85514. Adds a TestProperty to the current TestResult object when invoked in a context of a test, to current test case's ad_hoc_test_result when invoke from SetUpTestCase/TearDownTestCase, or to the global property set otherwise. If the result already contains a property with the same key, the value will be updated.

85515. class TestResult

85516. We don't want to run the initialization code twice.

85517. An escape sequence

85518. Determines whether a string has a prefix that Google Test uses for its flags, i.e., starts with GTEST_FLAG_PREFIX_ or GTEST_FLAG_PREFIX_DASH_. If Google Test detects that a command line flag has its prefix but is not recognized, it will print its help message. Flags starting with GTEST_INTERNAL_PREFIX_ followed by "internal_" are considered Google Test internal flags and do not trigger the help message.

85519. Non-inheritable.

85520. Routine for aborting the program which is safe to call from an exec-style death test child process, in which case the error message is propagated back to the parent process. Otherwise, the message is simply printed to stderr. In either case, the program then exits with status 1.

85521. GTEST_SRC_GTEST_INTERNAL_INL_H

85522. Resetting with the same handle we already own is invalid.

85523. Reads the GTEST_SHARD_STATUS_FILE environment variable, and creates the file if the variable is present. If a file already exists at this location, this function will write over it. If the variable is present, but the file cannot be created, prints an error and exits.

85524. Parses the environment variable var as an Int32. If it is unset, returns default_val. If it is not an Int32, prints an error and aborts.

85525. Waits for the child in a death test to exit, returning its exit status, or 0 if no child process exists. As a side effect, sets the outcome data member.

85526. Default security. Default stack size

85527. MINGW <time.h> provides neither localtime_r nor localtime_s, but uses Windows' localtime(), which has a thread-local tm buffer. NOLINT

85528. NOLINT NOLINT NOLINT NOLINT

85529. The vector of environments that need to be set-up/torn-down before/after the tests are run.

85530. Returns whether the given character is a valid path separator.

85531. Stops capturing stdout and returns the captured string.

85532. Reads the entire content of a file as a string.

85533. **comment:** WindowsDeathTest implements death tests on Windows. Due to the specifics of starting new processes on Windows, death tests there are always threadsafe, and Google Test considers the --gtest_death_test_style=fast setting to be equivalent to --gtest_death_test_style=threadsafethere. A few implementation notes: Like the Linux version, the Windows implementation uses pipes for child-to-parent communication. But due to the specifics of pipes on Windows, some extra steps are required: 1. The parent creates a communication pipe and stores handles to both ends of it. 2. The parent starts the child and provides it with the information necessary to acquire the handle to the write end of the pipe. 3. The child acquires the write end of the pipe and signals the parent using a Windows event. 4. Now the parent can release the write end of the pipe on its side. If this is done before step 3, the object's reference count goes down to 0 and it is destroyed, preventing the child from acquiring it. The parent now has to release it, or read operations on the read end of the pipe will not return when the child

terminates. 5. The parent reads child's output through the pipe (outcome code and any possible error messages) from the pipe, and its stderr and then determines whether to fail the test. Note: to distinguish Win32 API calls from the local method and function calls, the former are explicitly resolved in the global namespace.

label: code-design

85534. Prints a char c as if it's part of a string literal, escaping it when necessary; returns how c was formatted.

85535. Returns an XML-escaped copy of the input string str. If is_attribute is true, the text is meant to appear as an attribute value, and normalizable whitespace is preserved by replacing it with character references.

85536. class String.

85537. **comment:** GTEST_HAS_DEATH_TEST && !GTEST_OS_WINDOWS

label: test

85538. **comment:** There's no portable way to detect the number of threads, so we just return 0 to indicate that we cannot detect it.

label: code-design

85539. Looks up the human-readable system message for the HRESULT code and since we're not passing any params to FormatMessage, we don't want inserts expanded.

85540. Returns the test part result reporter for the current thread.

85541. Creates the test object.

85542. Finds and returns a TestCase with the given name. If one doesn't exist, creates one and returns it. Arguments: test_case_name: name of the test case type_param: the name of the test's type parameter, or NULL if this is not a typed or a type-parameterized test. set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case

85543. Helper functions for implementing IsSubString() and IsNotSubstring().

85544. Compares the name of each test with the user-specified filter to decide whether the test should be run, then records the result in each TestCase and TestInfo object. If shard_tests == true, further filters tests based on sharding variables in the environment - see

<http://code.google.com/p/googletest/wiki/GoogleTestAdvancedGuide>. Returns the number of tests that should run.

85545. There's no guarantee that a test has write access to the current directory, so we create the temporary file in the /tmp directory instead. We use /tmp on most systems, and /sdcard on Android. That's because Android doesn't have /tmp.

85546. Returns the type ID of ::testing::Test. We should always call this instead of GetTypeId< ::testing::Test>() to get the type ID of testing::Test. This is to work around a suspected linker bug when using Google Test as a framework on Mac OS X. The bug causes GetTypeId< ::testing::Test>() to return different values depending on whether the call is from the Google Test framework itself or from user test code. GetTestTypeId() is guaranteed to always return the same value, as it always calls GetTypeId<>() from the gtest.cc, which is within the Google Test framework.

85547. Returns the standard listener responsible for the default console output. Can be removed from the listeners list to shut down default console output. Note that removing this object from the listener list with Release transfers its ownership to the user.

85548. Registers thread_local_instance as having value on the current thread. Returns a value that can be used to identify the thread from other threads.

85549. Internal helper for printing the list of failed tests.

85550. Function for supporting the gtest_catch_exception flag.

85551. Conceptually, we split the string into segments divided by escape sequences. Then we print one segment at a time. At the end of each iteration, the str pointer advances to the beginning of the next segment.

85552. Utility functions for encoding Unicode text (wide strings) in UTF-8.

85553. Maps a thread to a set of ThreadIdToThreadLocals that have values instantiated on that thread and notifies them when the thread exits. A ThreadLocal instance is expected to persist until all threads it has values on have terminated.

85554. Will be overridden by the flag before first use.

85555. An empty regex matches a prefix of anything.

85556. **comment:** CodeGear C++Builder insists on a public destructor for the default implementation. Use this implementation to keep good OO design with private destructor.

label: code-design

85557. Iterates over a vector of TestCases, keeping a running sum of the results of calling a given int-returning method on each. Returns the sum.

85558. Internal helper functions for implementing the simple regular expression matcher.

85559. Matches the full name of each test against the user-specified filter to decide whether the test should run, then records the result in each TestCase and TestInfo object. If shard_tests == HONOR_SHARDING_PROTOCOL, further filters tests based on sharding variables in the environment. Returns the number of tests that should run.

85560. The default output file for XML output.

85561. Compares two C strings. Returns true iff they have the same content. Unlike strcmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.

85562. Names of the flags (needed for parsing Google Test flags).

85563. GTEST_USES_SIMPLE_RE

85564. If this file is included from the user's code, just say no.

85565. Returns true iff ch belongs to the given classification. Unlike similar functions in <ctype.h>, these aren't affected by the current locale.

85566. Implements the helper function for {ASSERT|EXPECT}_LT with int or enum arguments.

85567. NOLINT GTEST_OS_WINDOWS_MINGW

85568. Implemented as an explicit loop since std::count_if() in libCstd on Solaris has a non-standard signature.

85569. Command-line arguments for the child's call to exec File descriptor to close; the read end of a pipe

85570. Gets the number of failed tests.

85571. Destructor of UnitTest.

85572. Gets the number of all test cases.

85573. Returns a newly created InternalRunDeathTestFlag object with fields initialized from the GTEST_FLAG(internal_run_death_test) flag if the flag is specified; otherwise returns NULL.

85574. Returns true iff the test part non-fatally failed.

85575. Utility functions and classes used by the Google C++ testing framework. Author: wan@google.com (Zhanyong Wan) This file contains purely Google Test's internal implementation. Please DO NOT #INCLUDE IT IN A USER PROGRAM.

85576. Registers all parameterized tests defined using TEST_P and INSTANTIATE_TEST_CASE_P, creating regular tests for each test/parameter combination. This method can be called more than once; it has guards protecting from registering the tests more than once. If value-parameterized tests are disabled, RegisterParameterizedTests is present but does nothing.

85577. Streams test results to the given port on the given host machine.

85578. Sets the TestInfo object for the test that's currently running. If current_test_info is NULL, the assertion results will be stored in ad_hoc_test_result_.

85579. This 'if' can only be successful at most once, so theoretically we could break out of the loop here, but we don't bother doing so.

85580. A test whose test case name or test name matches this filter is disabled and not run.

85581. Makes a failed assertion result with the given failure message. Deprecated; use AssertionFailure() << message.

85582. **comment:** We make replace a little more expensive than add/remove to lower their priority.

label: code-design

85583. Constructor. TestNameIs has NO default constructor.

85584. Creates the test object, runs it, records its result, and then deletes it.

85585. Performs an in-place shuffle of a range of the vector's elements. 'begin' and 'end' are element indices as an STL-style range; i.e. [begin, end) are shuffled, where 'end' == size() means to shuffle to the end of the vector.

85586. Signals that the death test code which should have exited, didn't. Should be called only in a death test child process. Writes a status byte to the child's status file descriptor, then calls _exit(1).

85587. **comment:** Used by the GTEST_SUPPRESS_UNREACHABLE_CODE_WARNING_BELOW_ macro to suppress unreachable code warnings.

label: code-design

85588. Default security attributes. Do not reset automatically. Initially unset. Anonymous event.

85589. Protects access to GetThreadLocalsMapLocked() and its return value.

85590. namespace internal namespace testing Copyright 2008, Google Inc. All rights reserved. Author: wan@google.com (Zhangyong Wan)

85591. Generates non-fatal failures and returns false if regex is invalid; otherwise returns true.
85592. Implements the RE class.
85593. Configures listeners for XML output. This makes it possible for users to shut down the default XML output before invoking RUN_ALL_TESTS.
85594. Rounds up to 2-byte boundary.
85595. End of class Streaming Listener GTEST_CAN_STREAM_RESULTS_
85596. If a path to the premature-exit file is specified...
85597. Provides cross platform implementation for some death functionality.
85598. Returns true iff the current test has a non-fatal failure.
85599. # of bytes read in the last fread() # of bytes read so far
85600. The code const char kFoo[] = "foo"; generates an array of 4, not 3, elements, with the last one being '\0'. Therefore when printing a char array, we don't print the last element if it's '\0', such that the output matches the string literal as it's written in the source code.
85601. regfree'ing an invalid regex might crash because the content of the regex is undefined. Since the regex's are essentially the same, one cannot be valid (or invalid) without the other being so too.
85602. Runs all tests in this UnitTest object, prints the result, and returns true if all tests are successful. If any exception is thrown during a test, the test is considered to be failed, but the rest of the tests will still be run. When parameterized tests are enabled, it expands and registers parameterized tests first in RegisterParameterizedTests(). All other functions called from RunAllTests() may safely assume that parameterized tests are ready to be counted and run.
85603. **comment:** Valid only for fast death tests. Indicates the code is running in the child process of a fast style death test.
label: test
85604. On Windows, '\\' is the standard path separator, but many tools and the Windows API also accept '/' as an alternate path separator. Unless otherwise noted, a file path can contain either kind of path separators, or a mixture of them.
85605. Concrete class for actually writing strings to a socket.
85606. Returns true iff the wildcard pattern matches the string. The first ':' or '\0' character in pattern marks the end of it. This recursive algorithm isn't very efficient, but is clear and works well enough for matching test names, which are short.
85607. **comment:** Two fixture classes with the same name appear in two different namespaces, which is not allowed. Tell the user how to fix this.
label: code-design
85608. The regular expression which test output must match. DeathTestImpl doesn't own this object and should not attempt to delete it.
85609. Stores all ThreadIdToThreadLocals having values in a thread, indexed by thread's ID.
85610. Helpers for setting up / tearing down the given environment. They are for use in the ForEach() function.
85611. Helper function for implementing ASSERT_NEAR.
85612. End TestEventRepeater
85613. GTEST_HAS_DEATH_TEST
85614. class OsStackTraceGetter
85615. !GTEST_OS_WINDOWS_MOBILE
85616. Shuffles the tests inside each test case.
85617. Descriptor to the read end of the pipe to the child process. It is always -1 in the child process. The child keeps its write end of the pipe in write_fd_.
85618. Suppress clang analyzer warnings.
85619. Streams an XML representation of a TestInfo object.
85620. Parses a string for a string flag, in the form of "--flag=value". On success, stores the value of the flag in *value, and returns true. On failure, returns false without changing *value.
85621. Called in the parent process only. Reads the result code of the death test child process via a pipe, interprets it to set the outcome_ member, and closes read_fd_. Outputs diagnostics and terminates in case of unexpected codes.
85622. Stops capturing the output stream and returns the captured string.
85623. The working directory when the first TEST() or TEST_F() was executed.
85624. We print the help here instead of in RUN_ALL_TESTS(), as the latter may not be called at all if the user is using Google Test with another testing framework.
85625. namespace
85626. Formats the given time in milliseconds as seconds.
85627. MSVC and C++Builder do not provide a definition of STDERR_FILENO.
85628. MMAP_ANONYMOUS is not defined on Mac, so we use MAP_ANON instead.
85629. Compares two wide C strings. Returns true iff they have the same content. Unlike wcsncmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.
85630. UponLeavingGTest() should be called immediately before Google Test calls user code. It saves some information about the current stack that CurrentStackTrace() will use to find and hide Google Test stack frames.
85631. This class generates an XML output file.
85632. In a particular thread, maps a ThreadLocal object to its value.
85633. Prints the given C-string on a single line by replacing all '\n' characters with string "\n". If the output takes more than max_length characters, only prints the first max_length characters and "...".
85634. **comment:** Returns true iff test_case contains at least one test that should run.
label: test
85635. Returns true iff the test failed.
85636. "\\p" where p is pattern_char.
85637. Fields for saving the original values of flags.
85638. Gets the number of all test cases that contain at least one test that should run.
85639. Shuffles the non-death test cases.
85640. This condition is always false so AlwaysTrue() never actually throws, but it makes the compiler think that it may throw.
85641. **comment:** Spawns a child process with the same executable as the current process in a thread-safe manner and instructs it to run the death test. The implementation uses fork(2) + exec. On systems where clone(2) is available, it is used instead, being slightly more thread-safe. On QNX, fork supports only single-threaded environments, so this function uses spawn(2) there instead. The function dies with an error message if anything goes wrong.
label: code-design
85642. A macro for implementing the helper functions needed to implement ASSERT_?? and EXPECT_?? with integer or enum arguments. It is here just to avoid copy-and-paste of similar code.
85643. Returns the i-th element of the vector, or default_value if i is not in range [0, v.size()).
85644. NOLINT This exception type can only be thrown by a failed Google Test assertion with the intention of letting another testing framework catch it. Therefore we just re-throw it.
85645. **comment:** Gets the system's human readable message string for this HRESULT.
label: code-design
85646. Gets the time of the test program start, in ms from the start of the UNIX epoch.
85647. NOLINT NOLINT Declares vsnprintf(). This header is not available on Windows. NOLINT NOLINT NOLINT

85648. Determines if the arguments constitute UTF-16 surrogate pair and thus should be combined into a single Unicode code point using CreateCodePointFromUtf16SurrogatePair.
85649. GTEST_OS_WINDOWS && !defined(_GNUC_)
85650. Protects read and write access to global_test_part_result_reporter_.
85651. Yes. Inserts the test case after the last death test case defined so far. This only works when the test cases haven't been shuffled. Otherwise we may end up running a death test after a non-death test.
85652. **comment:** TODO(wan@google.com): on Windows \some\path is not an absolute path (as its meaning depends on the current drive), yet the following logic for turning it into an absolute path is wrong. Fix it.
label: code-design
85653. Does not return.
85654. **comment:** Print a unified diff header for one hunk. The format is "@@ -<left_start>,<left_length> +<right_start>,<right_length> @@" where the left/right parts are omitted if unnecessary.
label: code-design
85655. True iff PostFlagParsingInit() has been called.
85656. The private implementation of the UnitTest class. We don't protect the methods under a mutex, as this class is not accessible by a user and the UnitTest class that delegates work to this class does proper locking.
85657. Wait until the child either signals that it has acquired the write end of the pipe or it dies.
85658. A concrete death test class that forks and re-executes the main program from the beginning, with command-line flags set that cause only this specific death test to be run.
85659. Copyright 2008, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. Author: mheule@google.com (Markus Heule) Google C++ Testing Framework (Google Test) Sometimes it's desirable to build Google Test by compiling a single file. This file serves this purpose.
85660. Given directory = "dir", relative_path = "test.xml", returns "dir/test.xml". On Windows, uses \ as the separator rather than /.
85661. This predicate-formatter checks that 'results' contains a test part failure of the given type and that the failure message contains the given substring.
85662. Tears down the test fixture. A sub-class may override this.
85663. We are leaking the descriptor here because on some platforms (i.e., when built as Windows DLL), destructors of global objects will still run after calling _exit(). On such systems, write_fd_ will be indirectly closed from the destructor of UnitTestImpl, causing double close if it is also closed here. On debug configurations, double close may assert. As there are no in-process buffers to flush here, we are relying on the OS to close the descriptor after the process terminates when the destructors are not run. Exits w/o any normal exit hooks (we were supposed to crash)
85664. Formats an int value as "%X".
85665. namespace internal2
85666. class TestEventListeners
85667. The helper function for {ASSERT|EXPECT}_STRCASEEQ.
85668. Initializes an RE from its string representation.
85669. If input name has trailing separator character, remove it and return the name, otherwise return the name string unmodified. On Windows platform, uses \ as the separator, other platforms use /.
85670. GTEST_CAN_STREAM_RESULTS_
85671. Is a whitespace character that is normalized to a space character when it appears in an XML attribute value?
85672. Skips the pattern separator (the ':' character).
85673. Returns the output format, or "" for normal printed output.
85674. The parsed value overflows as a long. (strtol() returns LONG_MAX or LONG_MIN when the input overflows.)
85675. Returns the current application's name, removing directory path if that is present. Used by UnitTestOptions::GetOutputFile.
85676. regex isn't empty, isn't "\$", and doesn't start with a repetition. We match the first atom of regex with the first character of str and recurse.
85677. SetErrorMode doesn't exist on CE.
85678. MatchRepetitionAndRegexAtHead() calls MatchRegexAtHead(), so here's an indirect recursion. It terminates as the regex gets shorter in each recursion.
85679. **comment:** TODO(wan): report the reason of the failure. We don't do it for now as: 1. There is no urgent need for it. 2. It's a bit involved to make the errno variable thread-safe on all three operating systems (Linux, Windows, and Mac OS). 3. To interpret the meaning of errno in a thread-safe way, we need the strerror_r() function, which is not available on Windows.
label: requirement
85680. **comment:** task_threads allocates resources in thread_list and we need to free them to avoid leaks.
label: code-design
85681. PID of child process during death test; 0 in the child process itself.
85682. ForkingDeathTest provides implementations for most of the abstract methods of the DeathTest interface. Only the AssumeRole method is left undefined.
85683. Sets *value to the value of the flag.
85684. namespace internal namespace testing
85685. type_expr
85686. Converts the string value to a bool.
85687. The AssumeRole process for a Windows death test. It creates a child process with the same executable as the current process to run the death test. The child process is given the --gtest_filter and --gtest_internal_run_death_test flags such that it knows to run the current death test only.
85688. unit_test
85689. Returns the i-th test among all the tests. i can range from 0 to total_test_count() - 1. If i is not in that range, returns NULL.
85690. Returns the vector of environments that need to be set-up/torn-down before/after the tests are run.
85691. Returns true if FilePath ends with a path separator, which indicates that it is intended to represent a directory. Returns false otherwise. This does NOT check that a directory (or file) actually exists.
85692. **comment:** Converts the given time in milliseconds to a date string in the ISO 8601 format, without the timezone information. N.B.: due to the use of the non-reentrant localtime() function, this function is not thread safe. Do not use it in any code that can be called from multiple threads.
label: code-design
85693. MSVC compiler can be configured to define wchar_t as a typedef of unsigned short. Defining an overload for const wchar_t* in that case would cause pointers to unsigned shorts be printed as wide strings, possibly accessing more memory than intended and causing invalid memory accesses. MSVC defines _NATIVE_WCHAR_T_DEFINED symbol when wchar_t is implemented as a native type.
85694. Prints a (const) char/wchar_t array of 'len' elements, starting at address 'begin'. CharType must be either char or wchar_t.
85695. Disables event forwarding if the control is currently in a death test subprocess. Must not be called before InitGoogleTest.
85696. Returns a pointer to the last occurrence of a valid path separator in the FilePath. On Windows, for example, both "/" and "\\" are valid path separators. Returns NULL if no path separator was found.
85697. **comment:** Notifies the unit test event listener that a test has just finished.
label: test
85698. **comment:** Adds a test to this test case. Will delete the test upon destruction of the TestCase object.
label: test

85699. No error.
85700. **comment:** NOLINT - this is more readable than unbalanced brackets inside #if.
label: code-design
85701. Returns true if pathname describes a directory in the file-system that exists.
85702. Returns true iff regular expression re matches the entire str.
85703. GTEST_OS_QNX
85704. Converts a TestPartResult::Type enum to human-friendly string representation. Both kNonFatalFailure and kFatalFailure are translated to "Failure", as the user usually doesn't care about the difference between the two when viewing the test result.
85705. **comment:** An enumeration describing all of the possible ways that a death test can conclude. DIED means that the process died while executing the test code; LIVED means that process lived beyond the end of the test code; RETURNED means that the test statement attempted to execute a return statement, which is not allowed; THREW means that the test statement returned control by throwing an exception. IN_PROGRESS means the test has not yet concluded.
TODO(vladl@google.com): Unify names and possibly values for AbortReason, DeathTestOutcome, and flag characters above.
label: code-design
85706. Creates and returns a death test by dispatching to the current death test factory.
85707. The list of reserved attributes used in the <testsuites> element of XML output.
85708. Prints a wchar_t as a symbol if it is printable or as its internal code otherwise and also as its code. L'\0' is printed as "L'\\0'".
85709. Even if sharding is not on, test runners may want to use the GTEST_SHARD_STATUS_FILE to query whether the test supports the sharding protocol.
85710. Connect the client socket to the server socket.
85711. **comment:** Static mutexes are leaked intentionally. It is not thread-safe to try to clean them up. TODO(yukawa): Switch to Slim Reader/Writer (SRW) Locks, which requires nothing to clean it up but is available only on Vista and later. <http://msdn.microsoft.com/en-us/library/windows/desktop/aa904937.aspx>
label: requirement
85712. A helper class that creates the premature-exit file in its constructor and deletes the file in its destructor.
85713. Different Windows APIs may use either of these values to represent an invalid handle.
85714. Info about the first test in the current test case.
85715. Generates a textual failure message when a death test finds more than one thread running, or cannot determine the number of threads, prior to executing the given statement. It is the responsibility of the caller not to pass a thread_count of 1.
85716. Object that captures an output stream (stdout/stderr).
85717. A test filter that matches everything.
85718. GTEST_OS_LINUX
85719. AssertHelper constructor.
85720. **comment:** We want to call regcomp(&partial_regex_, ...) even if the previous expression returns false. Otherwise partial_regex_ may not be properly initialized can may cause trouble when it's freed. Some implementation of POSIX regex (e.g. on at least some versions of Cygwin) doesn't accept the empty string as a valid regex. We change it to an equivalent form "() to be safe.
label: code-design
85721. Previous character is of "x.." form and this character can be interpreted as another hexadecimal digit in its number. Break string to disambiguate.
85722. Formats a file location for compiler-independent XML output. Although this function is not platform dependent, we put it next to FormatFileLocation in order to contrast the two functions. Note that FormatCompilerIndependentFileLocation() does NOT append colon to the file location it produces, unlike FormatFileLocation().
85723. A predicate that checks the name of a TestCase against a known value. This is used for implementation of the UnitTest class only. We put it in the anonymous namespace to prevent polluting the outer namespace. TestCaseNameIs is copyable.
85724. Asserts that val1 is less than, or almost equal to, val2. Fails otherwise. In particular, it fails if either val1 or val2 is NaN.
85725. Clear the close-on-exec flag on the write end of the pipe, lest it be closed when the child process does an exec:
85726. Should not get here.
85727. The following lines pull in the real gtest *.cc files. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. Author: wan@google.com (Zhangyong Wan) The Google C++ Testing Framework (Google Test)
85728. Repeats the call to the post-flag parsing initialization in case the user didn't call InitGoogleTest.
85729. Generate unique file name.
85730. Captures the value of GTEST_FLAG(catch_exceptions). This value will be used for the duration of the program.
85731. GTEST_HAS_GLOBAL_WSTRING
85732. Configures listeners for streaming test results to the specified server.
85733. Gets the name of the TEST and the name of the TEST_F. Note that first_is_TEST and this_is_TEST cannot both be true, as the fixture IDs are different for the two tests.
85734. Deletes every Test in the collection.
85735. **comment:** Is this a death test case?
label: test
85736. The role interface for getting the OS stack trace as a string.
85737. If def_optional is true and there are more characters after the flag name, or if def_optional is false, there must be a '=' after the flag name.
85738. **comment:** Notifies the unit test event listeners that a test is about to start.
label: test
85739. This class saves the values of all Google Test flags in its c'tor, and restores them in its d'tor.
85740. using this in initializer
85741. This group of overloaded functions return true iff needle is a substring of haystack. NULL is considered a substring of itself only.
85742. Returns map of thread local instances.
85743. **comment:** Compares the full test names with the filter to decide which tests to run.
label: test
85744. On Windows, death tests are thread-safe regardless of the value of the death_test_style flag.
85745. Returns repeater that broadcasts the TestEventListener events to all subscribers.
85746. Set close_fd to be closed after spawn.
85747. Returns true iff the test name of test property matches on key_.
85748. Returns true iff ch appears anywhere in str (excluding the terminating '\0' character).
85749. Returns the number of elements in the given container that satisfy the given predicate.
85750. Parses the environment variable as a decimal integer.
85751. Points to (but doesn't own) the per-thread test part result reporter.
85752. Prints an XML representation of a TestCase object
85753. Converts a Unicode code point to a narrow string in UTF-8 encoding. code_point parameter is of type UInt32 because wchar_t may not be wide enough to contain a code point. If the code_point is not a valid Unicode code point (i.e. outside of Unicode range U+0 to U+10FFFF) it will be converted to "(Invalid Unicode 0xFFFFFFFF)".
85754. all done with this structure

85755. A copy of all command line arguments. Set by InitGoogleTest().
85756. Utilities needed for death tests.
85757. Returns a random seed in range [1, kMaxRandomSeed] based on the given --gtest_random_seed flag value.
85758. Points to (but doesn't own) the global test part result reporter.
85759. Child process handle.
85760. Returns the working directory when the first TEST() or TEST_F() was executed.
label: GTEST_OS_MAC
85762. no source, we're asking system the error no line width restrictions output buffer buf size no arguments for inserts Trims tailing white space (FormatMessage leaves a trailing CR-LF)
85763. The destructor of SingleFailureChecker verifies that the given TestPartResultArray contains exactly one failure that has the given type and contains the given substring. If that's not the case, a non-fatal failure will be generated.
85764. Default buffer size.
85765. Parses a string as a command line flag. The string should have the format "--flag=value". When def_optional is true, the "=value" part can be omitted. Returns the value of the flag, or NULL if the parsing failed.
label: GTEST_INCLUDE_GTEST_GTEST_SPI_H
85766. If the test part succeeded, we don't need to do anything.
85768. **comment:** Gets the number of disabled tests that will be reported in the XML report.
label: test
85769. The internal implementation of InitGoogleTest(). The type parameter CharType can be instantiated to either char or wchar_t.
85770. Loop through all the results and connect to the first we can.
85771. Used by UnitTest::Run() to capture the state of GTEST_FLAG(catch_exceptions) at the moment it starts.
85772. We print the type parameter on a single line to make the output easy to parse by a program.
85773. Returns the random seed used at the start of the current test run.
85774. Create directories so that path exists. Returns true if successful or if the directories already exist; returns false if unable to create directories for any reason.
85775. Returns the current application's name, removing directory path if that is present.
85776. Finds the next pattern in the filter.
85777. We have enough matches at the head, and the tail matches too. Since we only care about *whether* the pattern matches str (as opposed to *how* it matches), there is no need to find greedy match.
85778. Text printed in Google Test's text output and --gunit_list_tests output to label the type parameter and value parameter for a test.
85779. This macro is similar to GTEST_DEATH_TEST_CHECK_, but it is meant for evaluating any system call that fulfills two conditions: it must return -1 on failure, and set errno to EINTR when it is interrupted and should be tried again. The macro expands to a loop that repeatedly evaluates the expression as long as it evaluates to -1 and sets errno to EINTR. If the expression evaluates to -1 but errno is something other than EINTR, DeathTestAbort is called.
85780. Skips the stack frame for this function itself. NOLINT
85781. Do we see a Google Test flag?
85782. Find first edit.
85783. Restores the original test order after the iteration. This allows the user to quickly repro a failure that happens in the N-th iteration without repeating the first (N - 1) iterations. This is not enclosed in "if (GTEST_FLAG(shuffle)) { ... }", in case the user somehow changes the value of the flag somewhere (it's always safe to unshuffle the tests).
85784. Adds a failure if the key is a reserved attribute of the element named xml_element. Returns true if the property is valid.
85785. Signals the parent that the write end of the pipe has been acquired so the parent can release its own write end.
85786. Lists the tests and exits if the --gtest_list_tests flag was specified.
85787. Decrements the argument count.
85788. Gets the number of tests that should run.
85789. The list of event listeners that can be used to track events inside Google Test.
85790. size_t has the same width as pointers on both 32-bit and 64-bit Windows platforms. See <http://msdn.microsoft.com/en-us/library/tcxf1dw6.aspx>.
85791. Implements RE. Currently only needed for death tests.
85792. Returns true if pathname describes an absolute path.
85793. Reserves enough bytes to hold the regular expression used for a full match: we need space to prepend a '^', append a '\$', and terminate the string with '\0'.
85794. Reads and returns a 32-bit integer stored in the environment variable corresponding to the given flag; if it isn't set or doesn't represent a valid 32-bit integer, returns default_value.
85795. Does not own.
85796. We take "yes", "true", "t", and "1" as meaning "yes". If the value is neither one of these nor "auto", we treat it as "no" to be conservative.
85797. Convenience wrapper around EscapeXml when str is not an attribute value.
85798. Both help flag and unrecognized Google Test flags (excluding internal ones) trigger help display.
85799. Returns true if exit_status describes a process that was terminated by a signal, or exited normally with a nonzero exit code.
85800. A predicate that checks the key of a TestProperty against a known key. TestPropertyKeyIs is copyable.
85801. Gets the number of successful test cases.
85802. **comment:** TODO(wan): do not print the value of an expression if it's already a literal.
label: code-design
85803. GTEST_OS_WINDOWS_MOBILE || GTEST_OS_SYMBIAN || GTEST_OS_ZOS The '!= 0' comparison is necessary to satisfy MSVC 7.1.
85804. GTEST_OS_WINDOWS
85805. Convenience function for accessing the global UnitTest implementation object.
85806. Parses a string for an Int32 flag, in the form of "--flag=value". On success, stores the value of the flag in *value, and returns true. On failure, returns false without changing *value.
85807. The name of the file in which the death test is located.
85808. Protects access to GetThreadMapLocked() and its return value.
85809. Owned.
85810. Creates a Test object.
85811. On z/OS we additionally need strings.h for strcasecmp. NOLINT
85812. STL container utilities.
85813. **comment:** Returns the TestCase object for the test that's currently running, or NULL if no test is running.
label: test
85814. GTEST_HAS_STREAM_REDIRECTION
85815. Tells UnitTest where to store test result.
85816. A test is disabled if test case name or test name matches kDisableTestFilter.
85817. Reserves enough bytes to hold the regular expression used for a full match.
85818. Checks whether sharding is enabled by examining the relevant environment variable values. If the variables are present, but inconsistent (e.g., shard_index >= total_shards), prints an error and exits. If in_subprocess_for_death_test, sharding is disabled because it must only be applied to the original test process. Otherwise, we could filter out death tests we intended to execute.
85819. namespace internal
85820. Registers and returns a global test environment. When a test program is run, all global test environments will be set-up in the order they were registered. After all tests in the program have finished, all global test environments will be torn-down in the *reverse* order they were registered. The UnitTest object takes ownership of the given environment. We don't protect this under mutex_, as we only support calling it from the main thread.
85821. This is the default global test part result reporter used in UnitTestImpl. This class should only be used by UnitTestImpl.
85822. **comment:** Returns the given string with all characters invalid in XML removed. Currently invalid characters are dropped from the string. An alternative is to replace them with certain characters such as . or ?.
label: code-design
85823. This should be done before calling OnTestIterationStart(), such that a test event listener can see the actual test order in the event.

85824. Event the child process uses to signal the parent that it has acquired the handle to the write end of the pipe. After seeing this event the parent can release its own handles to make sure its ReadFile() calls return when the child terminates.
85825. num_runnable_tests are the number of tests that will run across all shards (i.e., match filter and are not disabled). num_selected_tests are the number of tests to be run on this shard.
85826. We cannot call abort() as it generates a pop-up in debug mode that cannot be suppressed in VC 7.1 or below.
85827. NOLINT NOLINT
85828. Monitors exit from a given thread and notifies those ThreadIdToThreadLocals about thread termination.
85829. This line ensures that gtest.h can be compiled on its own, even when it's fused.
85830. GTEST_OS_WINDOWS && !GTEST_OS_WINDOWS_MOBILE
85831. Fisher-Yates shuffle, from http://en.wikipedia.org/wiki/Fisher-Yates_shuffle
85832. The random number seed used at the beginning of the test run.
85833. **comment:** Gets the singleton UnitTest object. The first time this method is called, a UnitTest object is constructed and returned. Consecutive calls will return the same object. We don't protect this under mutex_ as a user is not supposed to call this before main() starts, from which point on the return value will never change.
label: code-design
85834. Returns the current working directory, or "" if unsuccessful.
85835. The ctor redirects the stream to a temporary file.
85836. To aid user debugging, we also print c's code in decimal, unless it's 0 (in which case c was printed as "\\0", making the code obvious).
85837. Creates a UTF-16 wide string from the given ANSI string, allocating memory using new. The caller is responsible for deleting the return value using delete[]. Returns the wide string, or NULL if the input is NULL.
85838. A stream to capture.
85839. This points to the TestInfo for the currently running test. It changes as Google Test goes through one test after another. When no test is running, this is set to NULL and Google Test stores assertion results in ad_hoc_test_result_. Initially NULL.
85840. Returns a pointer to the current death test factory.
85841. This function implements either IsSubstring() or IsNotSubstring(), depending on the value of the expected_to_be_substring parameter. StringType here can be const char*, const wchar_t*, ::std::string, or ::std::wstring.
85842. Returns true if c is a printable ASCII character. We test the value of c directly instead of calling isprint(), which is buggy on Windows Mobile.
85843. NOLINT
85844. The d'tor is not virtual. DO NOT INHERIT FROM THIS CLASS.
85845. Converts the buffer in a stringstream to an std::string, converting NUL bytes to "\\0" along the way.
85846. Helper function for IsHRESULT{SuccessFailure} predicates
85847. Waits for any of the handles.
85848. Returns true iff the name of test_case matches name_.
85849. Gets the summary of the failure message by omitting the stack trace in it.
85850. The following routines generate an XML representation of a UnitTest object. This is how Google Test concepts map to the DTD: <testsuites name="AllTests"> <-- corresponds to a UnitTest object <testsuite name="testcase-name"> <-- corresponds to a TestCase object <testcase name="test-name"> <-- corresponds to a TestInfo object <failure message="...">>...</failure> <failure message="...">>...</failure> <failure message="...">>...</failure> <-- individual assertion failures </testcase> </testsuite> </testsuites>
85851. **comment:** TODO(wan@google.com): on Windows a network share like \\server\share can be a root directory, although it cannot be the current directory. Handle this properly.
label: code-design
85852. Returns the number of threads running in the process, or 0 to indicate that we cannot detect it.
85853. The environment variable name for the test shard index.
85854. Do nothing.
85855. Somebody else is already initializing the mutex; spin until they are done.
85856. D'tor.
85857. We pass skip_count + 1 to skip this wrapper function in addition to what the user really wants to skip.
85858. When Google Test is built as a framework on MacOS X, the environ variable is unavailable. Apple's documentation (man environ) recommends using _NSGetEnviron() instead.
85859. GTEST_HAS_PARAM_TEST
85860. Repeats forever if the repeat count is negative.
85861. Attempts to parse a string into a positive integer pointed to by the number parameter. Returns true if that is possible. GTEST_HAS_DEATH_TEST implies that we have ::std::string, so we can use it here.
85862. Gets the elapsed time, in milliseconds.
85863. Sets up all environments beforehand.
85864. Windows CE doesn't support FormatMessage.
85865. Handle to the write end of the pipe to the child process.
85866. No - an invalid character was encountered.
85867. How long the test took to run, in milliseconds.
85868. Redirects all logging to stderr in the child process to prevent concurrent writes to the log files. We capture stderr in the parent process and append the child process' output to a log.
85869. GTEST_HAS_DEATH_TEST implies that we have ::std::string, so we can use it here.
85870. Formats a byte as "%02X".
85871. This function should not be called when the condition is false, but we provide a sensible default in case it is.
85872. The c'tor sets this object as the test part result reporter used by Google Test. The 'result' parameter specifies where to report the results.
85873. **comment:** Removes any redundant separators that might be in the pathname. For example, "bar//foo" becomes "bar/foo". Does not eliminate other redundancies that might be in a pathname involving "." or "...". TODO(wan@google.com): handle Windows network shares (e.g. \\server\share).
label: code-design
85874. GTEST_USES_POSIX_REGEX
85875. Note that the above two checks will both fail if either val1 or val2 is NaN, as the IEEE floating-point standard requires that any predicate involving a NaN must return false.
85876. Splits a given string on a given delimiter, populating a given vector with the fields. GTEST_HAS_DEATH_TEST implies that we have ::std::string, so we can use it here.
85877. namespace edit_distance
85878. **comment:** Unshuffles the tests in each test case.
label: test
85879. When a SIGPROF signal is received while fork() or clone() are executing, the process may hang. To avoid this, we ignore SIGPROF here and re-enable it after the call to fork()/clone() is complete.
85880. Adds an "exception thrown" fatal failure to the current test. This function returns its result via an output parameter pointer because VC++ prohibits creation of objects with destructors on stack in functions using __try (see error C2712).
85881. skip_count
85882. Prohibit instantiation.
85883. Google Test should handle a SEH exception if: 1. the user wants it to, AND 2. this is not a breakpoint exception, AND 3. this is not a C++ exception (VC++ implements them via SEH, apparently). SEH exception code for C++ exceptions. (see <http://support.microsoft.com/kb/185294> for more information).
85884. Sets the global test part result reporter.
85885. Provides access to the event listener list.
85886. Implements the TestPartResultReporterInterface. The implementation just delegates to the current global test part result reporter of *unit_test_
85887. Sets the OS stack trace getter. Does nothing if the input and the current OS stack trace getter are the same; otherwise, deletes the old getter and makes the input the current getter.

85888. Whole string is a positive filter
85889. We are done. We don't want this hunk.
85890. Outside the lock, let the destructor for 'value_holders' deallocate the ThreadLocalValueHolderBases.
85891. Returns true iff regular expression re matches a substring of str (including str itself).
85892. This string is inserted in place of stack frames that are part of Google Test's implementation.
85893. A set of macros for testing Google Test assertions or code that's expected to generate Google Test fatal failures. It verifies that the given statement will cause exactly one fatal Google Test failure with 'substr' being part of the failure message. There are two different versions of this macro. EXPECT_FATAL_FAILURE only affects and considers failures generated in the current thread and EXPECT_FATAL_FAILURE_ON_ALL_THREADS does the same but for all threads. The verification of the assertion is done correctly even when the statement throws an exception or aborts the current function. Known restrictions: - 'statement' cannot reference local non-static variables or non-static members of the current object. - 'statement' cannot return a value. - You cannot stream a failure message to this macro. Note that even though the implementations of the following two macros are much alike, we cannot refactor them to use a common helper macro, due to some peculiarity in how the preprocessor works. The AcceptsMacroThatExpandsToUnprotectedComma test in gtest_unittest.cc will fail to compile if we do that.
85894. Creates an empty UnitTest.
85895. Organizes the bytes into groups of 2 for easy parsing by human.
85896. namespace testing Copyright 2008 Google Inc. All Rights Reserved. Author: wan@google.com (Zhanyong Wan)
85897. Is the first thing in regex an escape sequence?
85898. This class implements the TestEvent Listener interface. Class PrettyUnitTestResultPrinter is copyable.
85899. Constructor. TestPropertyKeyIs has NO default constructor.
85900. Implements the helper function for {ASSERT|EXPECT}_LE with int or enum arguments.
85901. class TestInfo
85902. True iff we are in a subprocess for running a thread-safe-style death test.
85903. **comment:** Returns an indented copy of stderr output for a death test. This makes distinguishing death test output lines from regular log lines much easier.
label: code-design
85904. Returns the ANSI color code for the given color. COLOR_DEFAULT is an invalid input.
85905. Returns the value of GTEST_FLAG(catch_exceptions) at the moment UnitTest::Run() starts.
85906. **comment:** TODO(kenton@google.com): Use autoconf to detect availability of gettimeofday().
label: requirement
85907. Gets the text streamed to this object so far as an std::string. Each '\0' character in the buffer is replaced with "\\0".
85908. Prints the filter if it's not *. This reminds the user that some tests may be skipped.
85909. Indicates that this translation unit is part of Google Test's implementation. It must come before gtest-internal-inl.h is included, or there will be a compiler error. This trick exists to prevent the accidental inclusion of gtest-internal-inl.h in the user's code.
85910. Some POSIX platforms expect you to declare environ. extern "C" makes it reside in the global namespace.
85911. Parameter to ThreadMainStatic Default creation flags. Need a valid pointer for the call to work under Win98.
85912. Give the watcher thread the same priority as ours to avoid being blocked by it.
85913. Starts capturing stdout.
85914. Returns true iff the test fatally failed.
85915. Performs an in-place shuffle of the vector's elements.
85916. Pops a trace from the per-thread Google Test trace stack.
85917. Returns true iff the user-specified filter matches the test case name and the test name.
85918. See the comment in NoExecDeathTest::AssumeRole for why the next line is necessary.
85919. namespace testing Copyright 2008, Google Inc. All rights reserved. Author: wan@google.com (Zhanyong Wan)
85922. Parses the environment variable var as an Int32. If it is unset, returns default_val. If it is not an Int32, prints an error and aborts.
85923. **comment:** TODO(vladl@google.com): Factor the search functionality into Vector::Find.
label: code-design
85924. Replaces NUL with "\\0";
85925. Normally, a user only writes assertions inside a TEST or TEST_F, or inside a function called by a TEST or TEST_F. Since Google Test keeps track of which test is current running, it can associate such an assertion with the test it belongs to. If an assertion is encountered when no TEST or TEST_F is running, Google Test attributes the assertion result to an imaginary "ad hoc" test, and records the result in ad_hoc_test_result_.
85926. 10xxxxxx 10xxxxxx 1110xxxx code_point <= kMaxCodePoint4
85927. Returns true iff the unit test passed (i.e. all test cases passed).
85928. Streams an XML CDATA section, escaping invalid CDATA sequences as needed.
85929. The string representation of the values received in EqFailure() are already escaped. Split them on escaped "\n" boundaries. Leave all other escaped characters the same.

85930. To allow both IPv4 and IPv6 addresses.

85931. Initializes Google Test. This must be called before calling RUN_ALL_TESTS(). In particular, it parses a command line for the flags that Google Test recognizes. Whenever a Google Test flag is seen, it is removed from argv, and *argc is decremented. No value is returned. Instead, the Google Test flag variables are updated. Calling the function for the second time has no user-visible effect.

85932. Utility class for accumulating command-line arguments.

85933. Converts the given wide string to a narrow string using the UTF-8 encoding, and streams the result to this Message object.

85934. Returns the number of the test properties.

85935. Initializes owner_thread_id_ and critical_section_ in static mutexes.

85936. Returns the global test part result reporter.

85937. cpplint thinks that the header is already included, so we want to silence it. NOLINT

85938. All of these virtual functions are inherited from DeathTest.

85939. create the file with a single "0" character in it. I/O errors are ignored as there's nothing better we can do and we don't want to fail the test because of this.

85940. Prints a TestPartResult.

85941. The constructor of SingleFailureChecker remembers where to look up test part results, what type of failure we expect, and what substring the failure message should contain.

85942. There are two different ways to register your own TestPartResultReporter. You can register your own repoter to listen either only for test results from the current thread or for results from all threads. By default, each per-thread test result repoter just passes a new TestPartResult to the global test result reporter, which registers the test part result for the currently running test.

85943. Returns true if "name" matches the ':' separated list of glob-style filters in "filter".

85944. **comment:** Returns the TestResult for the ad hoc test.
label: test

85945. This defines a member that forwards the call to all listeners in reverse order.

85946. Tells UnitTest to stop associating assertion results to this test.

85947. The AssumeRole process for a fork-and-run death test. It implements a straightforward fork, with a simple pipe to transmit the status byte.

85948. Generates a random number from [0, range), using a Linear Congruential Generator (LCG). Crashes if 'range' is 0 or greater than kMaxRange.

85949. Pops the info pushed by the c'tor.

85950. Aborts if the parsing failed.

85951. Returns the name of the environment variable corresponding to the given flag. For example, FlagToEnvVar("foo") will return "GTEST_FOO" in the open-source version.

85952. namespace testing

85953. This is the default per thread test part result reporter used in UnitTestImpl. This class should only be used by UnitTestImpl.

85954. **comment:** Delegates to PrintBytesInObjectToImpl() to print the bytes in the given object. The delegation simplifies the implementation, which uses the << operator and thus is easier done outside of the ::testing::internal namespace, which contains a << operator that sometimes conflicts with the one in STL.
label: code-design

85955. The c'tor.

85956. The helper function for {ASSERT|EXPECT}_STREQ.

85957. spawn is a system call.

85958. **comment:** We don't call OutputDebugString*() on Windows Mobile, as printing to stdout is done by OutputDebugString() there already - we don't want the same message printed twice.
label: code-design

85959. Returns true if pathname describes a root directory. (Windows has one root directory per disk drive.)

85960. Declares the flags. We don't want the users to modify this flag in the code, but want Google Test's own unit tests to be able to access it. Therefore we declare it here as opposed to in gtest.h.

85961. The two possible mocking modes of this object.

85962. Performs initialization dependent upon flag values obtained in ParseGoogleTestFlagsOnly. Is called from InitGoogleTest after the call to ParseGoogleTestFlagsOnly. In case a user neglects to call InitGoogleTest this function is also called from RunAllTests. Since this function can be called more than once, it has to be idempotent.

85963. The c'tor sets this object as the test part result reporter used by Google Test. The 'result' parameter specifies where to report the results. Intercepts only failures from the current thread.

85964. Message assignment, for assertion streaming support.

85965. **comment:** Adds a test part result to the list.
label: test

85966. Big enough for the largest valid code point.

85967. If the test program runs in Visual Studio or a debugger, the following statements add the test part result message to the Output window such that the user can double-click on it to jump to the corresponding source code location; otherwise they do nothing.

85968. Shuffles test cases and tests if requested.

85969. Initializes event listeners performing XML output as specified by UnitTestOptions. Must not be called before InitGoogleTest.

85970. _WIN32_WCE

85971. Tells the user how big the object is.

85972. Runs the test and updates the test result.

85973. Escapes '=', '&', '%', and 'n' characters in str as "%xx".

85974. Flush the log buffers since the log streams are shared with the child.

85975. Finds and returns a TestCase with the given name. If one doesn't exist, creates one and returns it. It's the CALLER'S RESPONSIBILITY to ensure that this function is only called WHEN THE TESTS ARE NOT SHUFFLED. Arguments: test_case_name: name of the test case type_param: the name of the test case's type parameter, or NULL if this is not a typed or a type-parameterized test case. set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case

85976. Constructor.

85977. ParameterizedTestRegistry object used to register value-parameterized tests.

85978. Returns true iff "\c" is a supported escape sequence.

85979. ExitedWithCode function-call operator.

85980. The d'tor restores the previous test part result reporter.

85981. Returns if no more pattern can be found.

85982. Sends a string to the socket.

85983. Returns a copy of the FilePath with the case-insensitive extension removed. Example: FilePath("dir/file.exe").RemoveExtension("EXE") returns FilePath("dir/file"). If a case-insensitive extension is not found, returns a copy of the original FilePath.

85984. read_fd_ is expected to be closed and cleared by a derived class.

85985. Starts capturing an output stream (stdout/stderr).

85986. Copyright 2007, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE

POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhanyong Wan) Utilities for testing Google Test itself and code that uses Google Test (e.g. frameworks built on top of Google Test).

85987. Holds the thread id and thread handle that we pass from StartWatcherThreadFor to WatcherThreadFunc.

85988. No. Appends to the end of the list.

85989. Closes the socket.

85990. A Unicode code-point can have upto 21 bits, and is encoded in UTF-8 like this: Code-point length Encoding 0 - 7 bits 0xxxxxx 8 - 11 bits 110xxxxx 10xxxxxx 12 - 16 bits 1110xxxx 10xxxxxx 10xxxxxx 17 - 21 bits 11110xxx 10xxxxxx 10xxxxxx 10xxxxxx

85991. class StreamingListener

85992. Makes sure InitGoogleTest() was called.

85993. Reset count when a non match is found.

85994. Formats an int value as "%02d".

85995. Returns the absolute path of the requested output file, or the default (test_detail.xml in the original working directory) if none was explicitly specified.

85996. Adds a TestProperty to the current TestResult object when invoked in a context of a test or a test case, or to the global property set. If the result already contains a property with the same key, the value will be updated.

85997. **comment:** The main function for a threadsafe-style death test child process. This function is called in a clone()-ed process and thus must avoid any potentially unsafe operations like malloc or libc functions.

label: code-design

85998. Returns true iff the test part fatally failed.

85999. GTEST_OS_NACL

86000. Prints a wide or narrow char c as a character literal without the quotes, escaping it when necessary; returns how c was formatted. The template argument UnsignedChar is the unsigned version of Char, which is the type of c.

86001. Creates a concrete DeathTest-derived class that depends on the --gtest_death_test_style flag, and sets the pointer pointed to by the "test" argument to its address. If the test should be skipped, sets that pointer to NULL. Returns true, unless the flag is set to an invalid value.

86002. Windows CE doesn't have a current directory, so we just return something reasonable.

86003. GTEST_IMPLEMENTATION_

86004. 10xxxxxx 110xxxxx

86005. Restores the test cases and tests to their order before the first shuffle.

86006. Called after an assertion failure.

86007. Indicates whether RegisterParameterizedTests() has been called already.

86008. Keeps reading the file until we cannot read further or the pre-determined file size is reached.

86009. Runs the tests only if there was no fatal failure during global set-up.

86010. Makes a successful assertion result.

86011. Implements the helper function for {ASSERT|EXPECT}_NE with int or enum arguments.

86012. Constructs a TestInfo object. It assumes ownership of the test factory object.

86013. We are not on Windows.

86014. Google Test requires all tests in the same test case to use the same test fixture class. This function checks if the current test has the same fixture class as the first test in the current test case. If yes, it returns true; otherwise it generates a Google Test failure and returns false.

86015. **comment:** Gets the number of disabled tests in this test case.

label: test

86016. KilledBySignal constructor.

86017. Split --gtest_filter at ':', if there is one, to separate into positive filter and negative filter portions

86018. The maximum code-point a one-byte UTF-8 sequence can represent.

86019. Updates the critical_section_init_phase_ to 2 to signal initialization complete.

86020. Returns the TestResult containing information on test failures and properties logged outside of individual test cases.

86021. Either `:` or `^` marks the end of the pattern.

86022. Using DebugBreak on Windows allows gtest to still break into a debugger when a failure happens and both the --gtest_break_on_failure and the --gtest_catch_exceptions flags are specified.

86023. Get the number of tests in this test case that should run.

86024. Returns true iff the current test has a fatal failure.

86025. Tells the unit test event listeners that the tests are about to start.

86026. The list of reserved attributes used in the <testsuite> element of XML output.

86027. Restores the test order to before the first shuffle.

86028. Disable Microsoft deprecation warnings for POSIX functions called from this class (creat, dup, dup2, and close)

86029. Stops capturing stderr and returns the captured string.

86030. Skips the flag name.

86031. Controls whether events will be forwarded by the repeater to the listeners in the list.

86032. Returns true iff the given atom (specified by escaped and pattern) matches ch. The result is undefined if the atom is invalid.

86033. **comment:** On Windows the TERM variable is usually not set, but the console there does support colors.

label: code-design

86034. Returns the string after `=

86035. We print the value parameter on a single line to make the output easy to parse by a program.

86036. Class ScopedTrace

86037. No stack trace, either.

86038. Constructs a ForkingDeathTest.

86039. The environment variable name for the total number of test shards.

86040. Death test children can be terminated with _abort(). On Windows, _abort() can show a dialog with a warning message. This forces the abort message to go to stderr instead.

86041. Create a list of diff hunks in Unified diff format. Each hunk has a header generated by PrintHeader above plus a body with lines prefixed with '' for no change, '-' for deletion and '+' for addition. 'context' represents the desired unchanged prefix/suffix around the diff. If two hunks are close enough that their contexts overlap, then they are joined into one hunk.

86042. Both TEST and TEST_F appear in same test case, which is incorrect. Tell the user how to fix this.

86043. Retuned process handle is not inheritable. Retuned thread handle is not inheritable. Child inherits all inheritable handles (for write_handle_). Default creation flags. Inherit the parent's environment.

86044. Produces a string representing the test properties in a result as space delimited XML attributes based on the property key="value" pairs.

86045. Prints a ::wstring object.

86046. Reconstruct the best path. We do it in reverse order.

86047. **comment:** Helper function used by ValidateRegex() to format error messages.

label: code-design

86048. Comparing two pointers of which only one is NULL is undefined.

86049. Prints the given wide C string to the ostream.

86050. The read() here blocks until data is available (signifying the failure of the death test) or until the pipe is closed (signifying its success), so it's okay to call this in the parent before the child process has exited.

86051. Returns the TestPartResult at the given index (0-based).

86052. Returns EXCEPTION_EXECUTE_HANDLER if Google Test should handle the given SEH exception, or EXCEPTION_CONTINUE_SEARCH otherwise. This function is useful as an __except condition.

86053. The helper function for {ASSERT|EXPECT}_STRNE.

86054. Checks whether sharding is enabled by examining the relevant environment variable values. If the variables are present, but inconsistent (i.e., shard_index >= total_shards), prints an error and exits. If in_subprocess_for_death_test, sharding is disabled because it must only be applied to the original test process. Otherwise,

we could filter out death tests we intended to execute.

86055. Flushes the buffers and, if severity is GTEST_FATAL, aborts the program.

86056. Helper function for *_STRNE on wide strings.

86057. We can safely call chdir() as it's a direct system call.

86058. Find the first line to include in the hunk.

86059. The maximum code-point a four-byte UTF-8 sequence can represent.

86060. "\$" only matches the end of a string. Note that regex being valid guarantees that there's nothing after "\$" in it.

86061. **comment:** This function is a friend of UnitTest and as such has access to AddTestPartResult.

label: code-design

86062. On non-Windows platforms, we rely on the TERM variable.

86063. Formats the count of test cases.

86064. Gets the number of successful tests.

86065. Recreates the pipe and event handles from the provided parameters, signals the event, and returns a file descriptor wrapped around the pipe handle. This function is called in the child process only.

86066. The UnitTest object that owns this implementation object.

86067. Tears down all environments in reverse order afterwards.

86068. The event will automatically reset to non-signaled state. The initial state is non-signaled. The even is unnamed.

86069. Produces a string representing the test properties in a result as space delimited XML attributes based on the property key="value" pairs. When the std::string is not empty, it includes a space at the beginning, to delimit this attribute from prior attributes.

86070. Destroys a TestInfo object.

86071. The OS stack trace getter. Will be deleted when the UnitTest object is destructed. By default, an OsStackTraceGetter is used, but the user can set this field to use a custom getter if that is desired.

86072. Gets the number of failed test cases.

86073. This points to the TestCase for the currently running test. It changes as Google Test goes through one test case after another. When no test is running, this is set to NULL and Google Test stores assertion results in ad_hoc_test_result_. Initially NULL.

86074. A helper class for implementing EXPECT_FATAL_FAILURE() and EXPECT_NONFATAL_FAILURE(). Its destructor verifies that the given TestPartResultArray contains exactly one failure that has the given type and contains the given substring. If that's not the case, a non-fatal failure will be generated.

86075. The list of listeners that receive events.

86076. Prints the bytes in the given value to the given ostream.

86077. Will be overridden by the flag before first use. Will be reseeded before first use.

86078. ExitedWithCode constructor.

86079. Returns the size (in bytes) of a file.

86080. Windows CE doesn't have a current directory. You should not use the current directory in tests on Windows CE, but this at least provides a reasonable fallback.

86081. No info about the source file where the exception occurred. We have no info on which line caused the exception.

86082. Is the first test defined using TEST?

86083. Indicates that this translation unit is part of Google Test's implementation. It must come before gtest-internal-inl.h is included, or there will be a compiler error. This trick is to prevent a user from accidentally including gtest-internal-inl.h in his code.

86084. Sends the given message and a newline to the socket.

86085. We need to flush the stream buffers into the console before each SetConsoleTextAttribute call lest it affect the text that is already printed but has not yet reached the console.

86086. The default test part result reporters.

86087. Adds an "exception thrown" fatal failure to the current test.

86088. Resets the terminal to default. GTEST_OS_WINDOWS && !GTEST_OS_WINDOWS_MOBILE

86089. Creates an empty TestResult.

86090. The mutex is already initialized and ready for use.

86091. Note: Android applications are expected to call the framework's Context.getExternalStorageDirectory() method through JNI to get the location of the world-writable SD Card directory. However, this requires a Context handle, which cannot be retrieved globally from native code. Doing so also precludes running the code as part of a regular standalone executable, which doesn't run in a Dalvik process (e.g. when running it through 'adb shell'). The location /sdcard is directly accessible from native code and is the only location (unofficially) supported by the Android team. It's generally a symlink to the real SD Card mount point which can be /mnt/sdcard, /mnt/sdcard0, /system/media/sdcard, or other OEM-customized locations. Never rely on these, and always use /sdcard.

86092. Android, Mac OS X and Cygwin don't define wcscasecmp. Other unknown OSes may not define it either.

86093. GTEST_HAS_EXCEPTIONS

86094. The d'tor restores the test part result reporter used by Google Test before.

86095. Either the user wants Google Test to catch exceptions thrown by the tests or this is executing in the context of death test child process. In either case the user does not want to see pop-up dialogs about crashes - they are expected.

86096. **comment:** Shuffles all test cases, and the tests within each test case, making sure that death tests are still run first.

label: test

86097. Gets the i-th test case among all the test cases. i can range from 0 to total_test_case_count() - 1. If i is not in that range, returns NULL.

86098. (_MSC_VER == 1310 && !defined(_DEBUG)) || defined(__BORLANDC__)

86099. If critical_section_init_phase_ was 0 before the exchange, we are the first to test it and need to perform the initialization.

86100. **comment:** On a POSIX system, this function may be called from a threadsafe-style death test child process, which operates on a very small stack. Use the heap for any additional non-minuscule memory requirements.

label: code-design

86101. Not an escape sequence.

86102. GTestIsInitialized() returns true iff the user has initialized Google Test. Useful for catching the user mistake of not initializing Google Test before calling RUN_ALL_TESTS(). A user must call testing::InitGoogleTest() to initialize Google Test. g_init_gtest_count is set to the number of times InitGoogleTest() has been called. We don't protect this variable under a mutex as it is only accessed in the main thread.

86103. Deletes every TestCase.

86104. The maximum code-point a two-byte UTF-8 sequence can represent.

86105. substr_expr

86106. Returns the character attribute for the given color.

86107. We want to preserve failures generated by ad-hoc test assertions executed before RUN_ALL_TESTS().

86108. The line number on which the death test is located.

86109. A per-thread stack of traces created by the SCOPED_TRACE() macro.

86110. Gets the number of successful tests in this test case.

86111. Returns true iff the unit test failed (i.e. some test case failed or something outside of all tests failed).

86112. Reads and returns the Boolean environment variable corresponding to the given flag; if it's not set, returns default_value. The value is considered true iff it's not "0".

86113. The value of GetTestId() as seen from within the Google Test library. This is solely for testing GetTestId().

86114. The textual content of the code this object is testing. This class doesn't own this string and should not attempt to delete it.

86115. 0xxxxxxxx

86116. Runs each test case if there is at least one test to run.

86117. The constructor remembers the arguments.

86118. Swaps two AssertionResults.

86119. Compares two C strings, ignoring case. Returns true iff they have the same content. Unlike strcasecmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.

86120. Functions for processing the gtest_output flag.

86121. Sends a string and a newline to the socket.

86122. **comment:** TODO(yukawa): Consider to use _beginthreadex instead.
label: code-design
86123. **comment:** Two utility routines that together determine the direction the stack grows. This could be accomplished more elegantly by a single recursive function, but we want to guard against the unlikely possibility of a smart compiler optimizing the recursion away. GTEST_NO_INLINE_ is required to prevent GCC 4.6 from inlining StackLowerThanAddress into StackGrowsDown, which then doesn't give correct answer.
label: code-design
86124. Clean up the ThreadIdToThreadLocals data structure while holding the lock, but defer the destruction of the ThreadLocalValueHolderBases.
86125. Returns true iff the test has a non-fatal failure.
86126. True iff ?, *, or + can follow the previous atom.
86127. Sets the default_xml_generator attribute to the provided listener. The listener is also added to the listener list and previous default_xml_generator is removed from it and deleted. The listener can also be NULL in which case it will not be added to the list. Does nothing if the previous and the current listener objects are the same.
86128. Adds a TestProperty to the current TestResult object when invoked from inside a test, to current TestCase's ad_hoc_test_result_ when invoked from SetUpTestCase or TearDownTestCase, or to the global property set when invoked elsewhere. If the result already contains a property with the same key, the value will be updated.
86129. **comment:** Helper functions for naming files in a directory for xml output.
label: code-design
86130. We are on Windows CE.
86131. Abstract base class for writing strings to a socket.
86132. Returns the assertion's negation. Used with EXPECT/ASSERT_FALSE.
86133. Intercepts only thread local failures. Intercepts all failures.
86134. Treat '-test1' as the same as '*-test1'
86135. Found a match. Consume it.
86136. StringType here can be either ::std::string or ::std::wstring.
86137. Returns success if val1 is less than val2,
86138. Create the directory so that path exists. Returns true if successful or if the directory already exists; returns false if unable to create the directory for any reason, including if the parent directory does not exist. Not named ".CreateDirectory" because that's a macro on Windows.
86139. Controls whether events will be forwarded to listeners_. Set to false in death test child processes.
86140. Requested privileges ignored since DUPLICATE_SAME_ACCESS is used. Request non-inheritable handler.
86141. Creates a new XmlUnitTestResultPrinter.
86142. This overloaded version can be used in Windows programs compiled in UNICODE mode.
86143. Adds a test property to the list. If a property with the same key as the supplied property is already represented, the value of this test_property replaces the old value for that key.
86144. **comment:** How the death test concluded.
label: test
86145. These two overloads allow streaming a wide C string to a Message using the UTF-8 encoding.
86146. Clears the test part results.
86147. Given directory = "dir", base_name = "test", number = 0, extension = "xml", returns "dir/test.xml". If number is greater than zero (e.g., 12), returns "dir/test_12.xml". On Windows platform, uses \ as the separator rather than /.
86148. Populate for empty right.
86149. protects all internal state
86150. Helper class to convert string into ids with deduplication.
86151. Runs the given method and handles SEH exceptions it throws, when SEH is supported; returns the 0-value for type Result in case of an SEH exception. (Microsoft compilers cannot handle SEH and C++ exceptions in the same function. Therefore, we provide a separate wrapper function for handling SEH exceptions.)
86152. This method expands all parameterized tests registered with macros TEST_P and INSTANTIATE_TEST_CASE_P into regular tests and registers those. This will be done just once during the program runtime.
86153. Difference between 1970-01-01 and 1601-01-01 in milliseconds. <http://analogous.blogspot.com/2005/04/epoch.html>
86154. g_help_flag is true iff the --help flag or an equivalent form is specified on the command line.
86155. Normalizes the actual seed to range [1, kMaxRandomSeed] such that it's easy to type.
86156. We will run the test only if SetUp() was successful.
86157. Registers parameterized tests. This makes parameterized tests available to the UnitTest reflection API without running RUN_ALL_TESTS.
86158. Gets the number of all test parts. This is the sum of the number of successful test parts and the number of failed test parts.
86159. Constructs a failure message for Boolean assertions such as EXPECT_TRUE.
86160. Descriptor to the child's write end of the pipe to the parent process. It is always -1 in the parent process. The parent keeps its end of the pipe in read_fd_.
86161. Does nothing if the current thread holds the mutex. Otherwise, crashes with high probability.
86162. **comment:** A macro for testing Google Test assertions or code that's expected to generate Google Test non-fatal failures. It asserts that the given statement will cause exactly one non-fatal Google Test failure with 'substr' being part of the failure message. There are two different versions of this macro. EXPECT_NONFATAL_FAILURE only affects and considers failures generated in the current thread and EXPECT_NONFATAL_FAILURE_ON_ALL_THREADS does the same but for all threads. 'statement' is allowed to reference local variables and members of the current object. The verification of the assertion is done correctly even when the statement throws an exception or aborts the current function. Known restrictions: - You cannot stream a failure message to this macro. Note that even though the implementations of the following two macros are much alike, we cannot refactor them to use a common helper macro, due to some peculiarity in how the preprocessor works. If we do that, the code won't compile when the user gives EXPECT_NONFATAL_FAILURE() a statement that contains a macro that expands to code containing an unprotected comma. The AcceptsMacroThatExpandsToUnprotectedComma test in gtest_unittest.cc catches that. For the same reason, we have to write if (::testing::internal::AlwaysTrue() { statement; } instead of GTEST_SUPPRESS_UNREACHABLE_CODE_WARNING_BELOW_(statement) to avoid an MSVC warning on unreachable code.
label: code-design
86163. Matches any single character.
86164. Picks a new random seed for each iteration.
86165. Application pathname gotten in InitGoogleTest.
86166. **comment:** Implements the TestPartResultReporterInterface. Reports the test part result in the current test.
label: test
86167. Event forwarding to the listeners of event listener API must be shut down in death test subprocesses.
86168. Is this test defined using TEST?
86169. Fail fast if the given string does not begin with a digit; this bypasses strtoXXX's "optional leading whitespace and plus or minus sign" semantics, which are undesirable here.
86170. We don't protect writing to owner_thread_id_ here, as it's the caller's responsibility to ensure that the current thread holds the mutex when this is called.
86171. Initializes the event listener performing XML output as specified by UnitTestOptions. Must not be called before InitGoogleTest.
86172. Runs all tests in this UnitTest object and prints the result. Returns 0 if successful, or 1 otherwise. We don't protect this under mutex_, as we only support calling it from the main thread.
86173. If, however, the last element in the array is not '\0', e.g. const char kFoo[] = { 'f', 'o', 'o' }; we must print the entire array. We also print a message to indicate that the array is not NUL-terminated.
86174. Returns the list of event listeners that can be used to track events inside Google Test.
86175. Clear the following flags: pop-up window, core dump.
86176. We need to execute the test program in the same environment where it was originally invoked. Therefore we change to the original working directory first.
86177. Initializes event listeners for streaming test results in string form. Must not be called before InitGoogleTest.
86178. Resets the index of each test case.
86179. We know that the atom matches each of the first i characters in str.
86180. Print at most this many characters for each type/value parameter.

86181. We save the stack frame below the frame that calls user code. We do this because the address of the frame immediately below the user code changes between the call to UponLeavingGTest() and any calls to CurrentStackTrace() from within the user code.

86182. Matches any string (possibly empty) of characters.

86183. Applies a function/functor to each element in the container.

86184. Prints a TestPartResult to an std::string.

86185. Gets the number of tests to be printed in the XML report.

86186. The c'tor saves the values of all Google Test flags.

86187. Depending on the value of a char (or wchar_t), we print it in one of three formats: - as is if it's a printable ASCII (e.g. 'a', '2', ' '), - as a hexadecimal escape sequence (e.g. '\x7F'), or - as a special escape sequence (e.g. '\r', '\n').

86188. cpplint thinks that the header is already included, so we want to silence it. NOLINT NOLINT

86189. The child process will share the standard handles with the parent.

86190. **comment:** Can we find a TestCase with the given name?
label: test

86191. Starts capturing stderr.

86192. Populate for empty left.

86193. KilledBySignal function-call operator.

86194. Removes the given event listener from the list and returns it. It then becomes the caller's responsibility to delete the listener. Returns NULL if the listener is not found in the list.

86195. We need to pass a valid thread ID pointer into CreateThread for it to work correctly under Win98.

86196. BiggestConvertible is the largest integer type that system-provided string-to-number conversion routines can return.

86197. **comment:** TODO(vladl@google.com): Convert this to compile time assertion when it is available.
label: code-design

86198. Gets the result and clears it.

86199. results_expr

86200. GTEST_HAS_SEH

86201. We can safely call execve() as it's a direct system call. We cannot use execvp() as it's a libc function and thus potentially unsafe. Since execve() doesn't search the PATH, the user must invoke the test program via a valid path that contains at least one path separator.

86202. This must be called *after* FilterTests() has been called.

86203. Returns the number of TestPartResult objects in the array.

86204. GTEST_HAS_STD_WSTRING || GTEST_HAS_GLOBAL_WSTRING

86205. Constants.

86206. A predicate that checks the test name of a TestInfo against a known value. This is used for implementation of the TestCase class only. We put it in the anonymous namespace to prevent polluting the outer namespace. TestNameIs is copyable.

86207. Prints a wide or narrow character c and its code. '\0' is printed as "\\0", other unprintable characters are also properly escaped using the standard C++ escape sequence. The template argument UnsignedChar is the unsigned version of Char, which is the type of c.

86208. **comment:** We put these helper functions in the internal namespace as IBM's xlC compiler rejects the code if they were declared static.
label: code-design

86209. Transfers ownership.

86210. Called after the unit test ends.

86211. A replacement for CHECK that calls DeathTestAbort if the assertion fails.

86212. Returns a Boolean value indicating whether the caller is currently executing in the context of the death test child process. Tools such as Valgrind heap checkers may need this to modify their behavior in death tests. IMPORTANT: This is an internal utility. Using it may break the implementation of death tests. User code MUST NOT use it.

86213. Advance indices, depending on edit type.

86214. There is no next edit or it is too far away.

86215. Returns the first valid random seed after 'seed'. The behavior is undefined if 'seed' is invalid. The seed after kMaxRandomSeed is considered to be 1.

86216. Creates a TestCase with the given name. Arguments: name: name of the test case a_type_param: the name of the test case's type parameter, or NULL if this is not a typed or a type-parameterized test case. set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case

86217. Returns the current OS stack trace as an std::string. Parameters: max_depth - the maximum number of stack frames to be included in the trace. skip_count - the number of top frames to be skipped; doesn't count against max_depth.

86218. TestResult appropriate for property recording.

86219. **comment:** GTEST_IS_THREADSsafe && GTEST_OS_WINDOWS
label: test

86220. Flag characters for reporting a death test that did not die.

86221. Gets the current text color.

86222. If the object size is bigger than kThreshold, we'll have to omit some details by printing only the first and the last kChunkSize bytes. TODO(wan): let the user control the threshold using a flag.

86223. unit_test

86224. GTEST_OS_WINDOWS_MOBILE

86225. Parses a string for a bool flag, in the form of either "--flag=value" or "--flag". In the former case, the value is taken as true as long as it does not start with '0', 'f', or 'F'. In the latter case, the value is taken as true. On success, stores the value of the flag in *value, and returns true. On failure, returns false without changing *value.

86226. Verifies that registered_tests match the test names in defined_test_names_; returns registered_tests if successful, or aborts the program otherwise.

86227. Provides a level of indirection for the test case list to allow easy shuffling and restoring the test case order. The i-th element of this vector is the index of the i-th test case in the shuffled order.

86228. Returns a pointer to the parsed --gtest_internal_run_death_test flag, or NULL if that flag was not specified. This information is useful only in a death test child process. Must not be called before a call to InitGoogleTest.

86229. Default security. Default stack size.

86230. socket file descriptor

86231. For strtoll/_strtoul64/malloc/free. For memmove.

86232. TestResult contains some private methods that should be hidden from Google Test user but are required for testing. This class allows our tests to access them. This class is supplied only for the purpose of testing Google Test's own constructs. Do not use it in user tests, either directly or indirectly.

86233. Returns the given string with all characters invalid in XML removed.

86234. Prints the names of the tests matching the user-specified filter flag.

86235. The environment variable is not set.

86236. namespace testing Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhanyong Wan), vladl@google.com (Vlad Losev) This file implements death tests.

86237. The maximum code-point a three-byte UTF-8 sequence can represent.
86238. GTEST_OS_LINUX_ANDROID
86239. Chops off the n lowest bits from a bit pattern. Returns the n lowest bits. As a side effect, the original bit pattern will be shifted to the right by n bits.
86240. Appends the user-supplied message to the Google-Test-generated message.
86241. Returns the i-th test part result among all the results. i can range from 0 to total_part_count() - 1. If i is not in that range, aborts the program.
86242. The flag must start with "--" followed by GTEST_FLAG_PREFIX_.
86243. class TestCase
86244. Pushes the given source file location and message onto a per-thread trace stack maintained by Google Test.
86245. Convenience wrapper around EscapeXml when str is an attribute value.
86246. Runs every test in this TestCase.
86247. 10xxxxxx 10xxxxxx 10xxxxxx 11110xxx
86248. Called at the start of streaming to notify the receiver what protocol we are using.
86249. Utilities
86250. Do not run any test if the --help flag was specified.
86251. This generic version is used when k is 0.
86252. class CartesianProductGenerator3
86253. Type and function utilities for implementing parameterized tests.
86254. Generates a random number from [0, range). Crashes if 'range' is 0 or greater than kMaxRange.
86255. A test case, which consists of a vector of TestInfos. TestCase is not copyable.
86256. A compile-time bool constant that is true if and only if x is a null pointer literal (i.e. NULL or any 0-valued compile-time integral constant).
86257. These two compilers are known to support SEH.
86258. Makes sure T is a complete type.
86259. Inside a test, refer to TypeParam to get the type parameter.
86260. Then prints the value itself.
86261. Declares the flags.
86262. Sets the should_run member.
86263. Implements printing a non-reference type T by letting the compiler pick the right overload of PrintTo() for T.
86264. Appends an event listener to the end of the list. Google Test assumes the ownership of the listener (i.e. it will delete the listener when the test program finishes).
86265. GTEST_INCLUDE_GTEST_GTEST_H
86266. Compares two wide C strings, ignoring case. Returns true iff they have the same content. Unlike wcscasecmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL wide C string, including the empty string. NB: The implementations on different platforms slightly differ. On windows, this method uses _wcsicmp which compares according to LC_CTYPE environment variable. On GNU platform this method uses wcscasecmp which compares according to LC_CTYPE category of the current locale. On MacOS X, it uses towlower, which also uses LC_CTYPE category of the current locale.
86267. Defines the abstract factory interface that creates instances of a Test object.
86268. EXPECT_DEBUG_DEATH asserts that the given statements die in debug mode. The death testing framework causes this to have interesting semantics, since the sideeffects of the call are only visible in opt mode, and not in debug mode. In practice, this can be used to test functions that utilize the LOG(DFATAL) macro using the following style: int DieInDebugOr12(int* sideeffect) { if (sideeffect) { *sideeffect = 12; } LOG(DFATAL) << "death"; return 12; } TEST(TestCase, TestDieOr12WorksInDbgAndOpt) { int sideeffect = 0; // Only asserts in dbg. EXPECT_DEBUG_DEATH(DieInDebugOr12(&sideeffect), "death"); #ifdef NDEBUG // opt-mode has sideeffect visible. EXPECT_EQ(12, sideeffect); #else // dbg-mode no visible sideeffect. EXPECT_EQ(0, sideeffect); #endif } This will assert that DieInDebugReturn12InOpt() crashes in debug mode, usually due to a DCHECK or LOG(DFATAL), but returns the appropriate fallback value (12 in this case) in opt mode. If you need to test that a function has appropriate side-effects in opt mode, include assertions against the side-effects. A general pattern for this is: EXPECT_DEBUG_DEATH({ // Side-effects here will have an effect after this statement in // opt mode, but none in debug mode. EXPECT_EQ(12, DieInDebugOr12(&sideeffect)); }, "death");
86269. t2
86270. #ifdef __GNUC__ is too general here. It is possible to use gcc without using libstdc++ (which is where cxxabi.h comes from).
86271. class CartesianProductGenerator9::Iterator
86272. Returns the elapsed time, in milliseconds.
86273. Initializes this object with a copy of the input.
86274. Overloads for wide C strings
86275. **comment:** We print a protobuf using its ShortDebugString() when the string doesn't exceed this many characters; otherwise we print it using DebugString() for better readability.
label: code-design
86276. Provides a level of indirection for the test list to allow easy shuffling and restoring the test order. The i-th element in this vector is the index of the i-th test in the shuffled test list.
86277. The test failure summary. The test failure message.
86278. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. Authors: wan@google.com (Zhangyong Wan) Low-level types and utilities for porting Google Test to various platforms. All macros ending with _ and symbols defined in an internal namespace are subject to change without notice. Code outside Google Test MUST NOT USE THEM DIRECTLY. Macros that don't end with _ are part of Google Test's public API and can be used by code outside Google Test. This file is fundamental to Google Test. All other Google Test source files are expected to #include this. Therefore, it cannot #include any other Google Test header.
86279. class CartesianProductHolder5
86280. When this flag is specified, a failed assertion will throw an exception if exceptions are enabled, or exit the program with a non-zero code otherwise.
86281. 'index' is the index of the test in the type list 'Types' specified in INSTANTIATE_TYPED_TEST_CASE_P(Prefix, TestCase, Types). Valid values for 'index' are [0, N - 1] where N is the length of Types.
86282. GTEST_HAS_TYPED_TEST_P
86283. Formats a source file path and a line number as they would appear in an error message from the compiler used to compile this code.
86284. class ValuesInIteratorRangeGenerator
86285. CopyArray() copies a k-dimensional native array using the elements' operator=, where k can be any integer ≥ 0 . When k is 0, CopyArray() degenerates into copying a single value.
86286. A dummy implementation of synchronization primitives (mutex, lock, and thread-local variable). Necessary for compiling Google Test where mutex is not supported - using Google Test in multiple threads is not supported on such platforms.
86287. **comment:** Adds a failure if the key is a reserved attribute of Google Test testcase tags. Returns true if the property is valid. TODO(russr): Validate attribute names are legal and human readable.
label: code-design
86288. Sets the default_result_printer attribute to the provided listener. The listener is also added to the listener list and previous default_result_printer is removed from it and deleted. The listener can also be NULL in which case it will not be added to the list. Does nothing if the previous and the current listener objects are the same.
86289. __GNUC__ && (GTEST_GCC_VER_ \geq 30400) && !COMPILER_ICC

86290. **comment:** Prints the given value to the given ostream. If the value is a protocol message, its debug string is printed; if it's an enum or of a type implicitly convertible to BiggestInt, it's printed as an integer; otherwise the bytes in the value are printed. This is what UniversalPrinter<T>::Print() does when it knows nothing about type T and T has neither << operator nor PrintTo(). A user can override this behavior for a class type Foo by defining a << operator in the namespace where Foo is defined. We put this operator in namespace 'internal' instead of 'internal' to simplify the implementation, as much code in 'internal' needs to use << in STL, which would conflict with our own << were it defined in 'internal'. Note that this operator<< takes a generic std::basic_ostream<Char, CharTraits> type instead of the more restricted std::ostream. If we define it to take an std::ostream instead, we'll get an "ambiguous overloads" compiler error when trying to print a type Foo that supports streaming to std::basic_ostream<Char, CharTraits>, as the compiler cannot tell whether operator<<(std::ostream&, const T&) or operator<<(std::basic_stream<Char, CharTraits>, const Foo&) is more specific.

label: code-design

86291. You can implement all the usual class fixture members here.

86292. Take over ownership of a raw pointer. This should happen as soon as possible after the object is created.

86293. Initializes this object with a reference of the input.

86294. DeathTest is a class that hides much of the complexity of the GTEST_DEATH_TEST macro. It is abstract; its static Create method returns a concrete class that depends on the prevailing death test style, as defined by the --gtest_death_test_style and/or --gtest_internal_run_death_test flags.

86295. __GXX_RTTI

86296. Returns true iff the current test has a (either fatal or non-fatal) failure.

86297. **comment:** Separate the error generating code from the code path to reduce the stack frame size of CmpHelperOP. This helps reduce the overhead of some sanitizers when calling EXPECT_OP in a tight loop.

label: code-design

86298. class CartesianProductHolder4

86299. Fired before any test activity starts.

86300. UnitTest class invokes this method to register tests in this test case right before running them in RUN_ALL_TESTS macro. This method should not be called more than once on any single instance of a ParameterizedTestCaseInfoBase derived class.

86301. GTEST_INCLUDE_GTEST_GTEST_TEST_PART_H Copyright 2008 Google Inc. All Rights Reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhangyong Wan)

86302. Implements thread-local storage on Windows systems. // Thread 1 ThreadLocal<int> tl(100); // 100 is the default value for each thread. // Thread 2 tl.set(150); // Changes the value for thread 2 only. EXPECT_EQ(150, tl.get()); // Thread 1 EXPECT_EQ(100, tl.get()); // In thread 1, tl has the original value. tl.set(200); EXPECT_EQ(200, tl.get()); The template type argument T must have a public copy constructor. In addition, the default ThreadLocal constructor requires T to have a public default constructor. The users of a ThreadLocal instance have to make sure that all but one threads (including the main one) using that instance have exited before destroying it. Otherwise, the per-thread objects managed for them by the ThreadLocal instance are not guaranteed to be destroyed on all platforms. Google Test only uses global ThreadLocal objects. That means they will die after main() has returned. Therefore, no per-thread object managed by Google Test will be leaked as long as all threads using Google Test have exited when main() returns.

86303. Typed tests need <typeinfo> and variadic macros, which GCC, VC++ 8.0, Sun Pro CC, IBM Visual Age, and HP aCC support.

86304. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE DIRECTLY. Expands to the name of the variable used to remember the names of the registered tests in the given test case.

86305. Allows a controller thread to pause execution of newly created threads until notified. Instances of this class must be created and destroyed in the controller thread. This class is only for testing Google Test's own constructs. Do not use it in user tests, either directly or indirectly.

86306. Starting with version 4.3.2, gcc defines __GXX_RTTI iff RTTI is enabled.

86307. STL-style container methods.

86308. class CartesianProductGenerator2::Iterator

86309. **comment:** Tell the compiler to warn about unused return values for functions declared with this macro. The macro should be used on function declarations following the argument list: Sprocket* AllocateSprocket() GTEST_MUST_USE_RESULT_;

label: code-design

86310. The vector of TestPartResults

86311. A secret type that Google Test users don't know about. It has no definition on purpose. Therefore it's impossible to create a Secret object, which is what we want.

86312. Constructs and returns the message for an equality assertion (e.g. ASSERT_EQ, EXPECT_STREQ, etc) failure. The first four parameters are the expressions used in the assertion and their values, as strings. For example, for ASSERT_EQ(foo, bar) where foo is 5 and bar is 6, we have: expected_expression: "foo" actual_expression: "bar" expected_value: "5" actual_value: "6" The ignoring_case parameter is true iff the assertion is a *_STRCASEEQ*. When it's true, the string "(ignoring case)" will be inserted into the message.

86313. Internal macro for implementing {EXPECT|ASSERT}_PRED5. Don't use this in your code.

86314. This assumes that non-Windows OSes provide unistd.h. For OSes where this is not the case, we need to include headers that provide the functions mentioned above.

86315. GTEST_HAS_RTTI

86316. GTEST_HAS_CLONE

86317. **comment:** FullMatch(str, re) returns true iff regular expression re matches the entire str. PartialMatch(str, re) returns true iff regular expression re matches a substring of str (including str itself). TODO(wan@google.com): make FullMatch() and PartialMatch() work when str contains NUL characters.

label: code-design

86318. Helpers for ThreadLocal.

86319. Defines RE.

86320. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. ParameterizedTestCaseInfoBase is a generic interface to ParameterizedTestCaseInfo classes. ParameterizedTestCaseInfoBase accumulates test information provided by TEST_P macro invocations and generators provided by

INSTANTIATE_TEST_CASE_P macro invocations and uses that information to register all resulting test instances in RegisterTests method. The ParameterizeTestCaseRegistry class holds a collection of pointers to the ParameterizedTestCaseInfo objects and calls RegisterTests() on each of them when asked.

86321. If *pstr starts with the given prefix, modifies *pstr to be right past the prefix and returns true; otherwise leaves *pstr unchanged and returns false. None of pstr, *pstr, and prefix can be NULL.

86322. Called by pthread to delete thread-local data stored by pthread_setspecific().

86323. The helper function for {ASSERT|EXPECT}_STRNE. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86324. **comment:** Formats a file location for compiler-independent XML output. Although this function is not platform dependent, we put it next to FormatFileLocation in order to contrast the two functions.

label: code-design

86325. Determines whether test results can be streamed to a socket.

86326. **comment:** The friend relationship of some of these classes is cyclic. If we don't forward declare them the compiler might confuse the classes in friendship clauses with same named classes on the scope.

label: code-design

86327. This specialization is used when the first argument to ASSERT_EQ() is a null pointer literal, like NULL, false, or 0.

86328. Destructor of TestCase.

86329. Determines whether Google Test can use tr1/tuple. You can define this macro to 0 to prevent Google Test from using tuple (any feature depending on tuple with be disabled in this mode).

86330. The maximum number of elements to print.
86331. ID of the test fixture class True iff this test should run True iff this test is disabled True if this test matches the user-specified filter. The factory that creates the test object
86332. The text used in failure messages to indicate the start of the stack trace.
86333. The thread holding the mutex.
86334. Used to print an STL-style container when the user doesn't define a PrintTo() for it.
86335. class CartesianProductHolder7
86336. This flag controls whether Google Test emits a detailed XML report to a file in addition to its normal textual output.
86337. No type parameter.
86338. Unary predicate assertion macros.
86339. Stat(), RmDir(), and IsDir() are not needed on Windows CE at this time and thus not defined there.
86340. Given directory = "dir", relative_path = "test.xml", returns "dir/test.xml". On Windows, uses \ as the separator rather than /.
86341. Sets up, executes, and tears down the test.
86342. Returns the result of the test.
86343. TestEventListeners lets users add listeners to track events in Google Test.
86344. namespace gtest_internal
86345. When a thread exits, DeleteThreadLocalValue() will be called on the object managed for that thread.
86346. gcc defines __EXCEPTIONS to 1 iff exceptions are enabled.
86347. A simple Linear Congruential Generator for generating random numbers with a uniform distribution. Unlike rand() and srand(), it doesn't use global state (and therefore can't interfere with user code). Unlike rand_r(), it's portable. An LCG isn't very random, but it's good enough for our purposes.
86348. If the type list contains only one type, you can write that type directly without Types<...>: INSTANTIATE_TYPED_TEST_CASE_P(My, FooTest, int);
86349. Tears down the test fixture.
86350. Sun Pro CC supports exceptions. However, there is no compile-time way of detecting whether they are enabled or not. Therefore, we assume that they are enabled unless the user tells us otherwise.
86351. State of the definition of a type-parameterized test case.
86352. Returns true iff the test is disabled and will be reported in the XML report.
86353. Releases resources associated with the key. This will *not* delete managed objects for other threads.
86354. Fired before the test case starts.
86355. Returns true iff the test case failed.
86356. The user didn't tell us not to do it, so we assume it's OK.
86357. line
86358. Instead of 1/0, we want to see true/false for bool values.
86359. GTEST_HAS_PTHREAD && !GTEST_OS_WINDOWS_MINGW
86360. This flag controls whether Google Test catches all test-thrown exceptions and logs them as failures.
86361. Returns the test case name.
86362. GTEST_HAS_STD_MOVE_
86363. Gets the number of all tests.
86364. signed/unsigned mismatch
86365. Helper function for implementing {EXPECT|ASSERT}_PRED4. Don't use this in your code.
86366. STL-style container typedefs.
86367. Logs a property for the current test, test case, or for the entire invocation of the test program when used outside of the context of a test case. Only the last value for a given key is remembered. These are public static so they can be called from utility functions that are not members of the test fixture. Calls to RecordProperty made during lifespan of the test (from the moment its constructor starts to the moment its destructor finishes) will be output in XML as attributes of the < testcase > element. Properties recorded from fixture's SetUpTestCase or TearDownTestCase are logged as attributes of the corresponding < testsuite > element. Calls to RecordProperty made in the global context (before or after invocation of RUN_ALL_TESTS and from SetUp/TearDown method of Environment objects registered with Google Test) will be output as attributes of the < testsuites > element.
86368. Sets up the test fixture.
86369. Returns true iff test is disabled.
86370. **comment:** A TestInfo object stores the following information about a test: Test case name Test name Whether the test should be run A function pointer that creates the test object when invoked Test result The constructor of TestInfo registers itself with the UnitTest singleton such that the RUN_ALL_TESTS() macro knows which tests to run.
label: test
86371. Pushes a trace defined by SCOPED_TRACE() on to the per-thread Google Test trace stack.
86372. **comment:** Provides leak-safe Windows kernel handle ownership. Used in death tests and in threading support.
label: code-design
86373. The user didn't tell us, so we need to figure it out.
86374. Gets the number of failed tests in this test case.
86375. Defining a variable of type CompileAssertTypesEqual<T1, T2> will cause a compiler error iff T1 and T2 are different types.
86376. Returns a pathname for a file that does not currently exist. The pathname will be directory/base_name.extension or directory/base_name_<number>.extension if directory/base_name.extension already exists. The number will be incremented until a pathname is found that does not already exist. Examples: 'dir/foo_test.xml' or 'dir/foo_test_1.xml'. There could be a race condition if two or more processes are calling this function at the same time -- they could both pick the same filename.
86377. **comment:** Parses 'str' for a 32-bit signed integer. If successful, writes the result to *value and returns true; otherwise leaves *value unchanged and returns false.
TODO(chandlerc): Find a better way to refactor flag and environment parsing out of both gtest-port.cc and gtest.cc to avoid exporting this utility function.
label: code-design
86378. **comment:** To write value-parameterized tests, first you should define a fixture class. It is usually derived from testing::TestWithParam<T> (see below for another inheritance scheme that's sometimes useful in more complicated class hierarchies), where the type of your parameter values. TestWithParam<T> is itself derived from testing::Test. T can be any copyable type. If it's a raw pointer, you are responsible for managing the lifespan of the pointed values.
label: code-design
86379. The thread can be created only after all fields except thread_ have been initialized.
86380. GTEST_IS_THREADSAFE
86381. Returns a copy of the FilePath with the directory part removed. Example: FilePath("path/to/file").RemoveDirectoryName() returns FilePath("file"). If there is no directory part ("just_a_file"), it returns the FilePath unmodified. If there is no file part ("just_a_dir") it returns an empty FilePath (""). On Windows platform, \ is the path separator, otherwise it is '/'.
86382. It's a NAN if the exponent bits are all ones and the fraction bits are not entirely zeros.
86383. Static methods
86384. TypeParameterizedTest<Fixture, TestSel, Types>::Register() registers a list of type-parameterized tests with Google Test. The return value is insignificant - we just need to return something such that we can call this function in a namespace scope. Implementation note: The GTEST_TEMPLATE_ macro declares a template template parameter. It's defined in gtest-type-util.h.
86385. Acquires this mutex.
86386. LocalTestInfo structure keeps information about a single test registered with TEST_P macro.
86387. **comment:** Defines logging utilities: GTEST_LOG_(severity) - logs messages at the specified severity level. The message itself is streamed into the macro. LogToStderr() - directs all log messages to stderr. FlushInfoLog() - flushes informational log messages.
label: code-design
86388. Creates an ANSI string from the given wide string, allocating memory using new. The caller is responsible for deleting the return value using delete[]. Returns the ANSI string, or NULL if the input is NULL. The returned string is created using the ANSI codepage (CP_ACP) to match the behaviour of the ANSI versions of Win32 calls and the C runtime.
86389. Determines the platform on which Google Test is compiled.

86390. Implements the helper function for {ASSERT|EXPECT}_LT
86391. These two functions are overloaded. Given an expression Helper(x), the compiler will pick the first version if x can be implicitly converted to type To; otherwise it will pick the second version. The first version returns a value of size 1, and the second version returns a value of size 2. Therefore, by checking the size of Helper(x), which can be done at compile time, we can tell which version of Helper() is used, and hence whether x can be implicitly converted to type To.
86392. Return value used only to run this method in namespace scope.
86393. Returns the text representation of the value parameter, or NULL if this is not a value-parameterized test.
86394. We use our own TR1 tuple if we aren't sure the user has an implementation of it already. At this time, libstdc++ 4.0.0+ and MSVC 2010 are the only mainstream standard libraries that come with a TR1 tuple implementation. NVIDIA's CUDA NVCC compiler pretends to be GCC by defining __GNUC__ and friends, but cannot compile GCC's tuple implementation. MSVC 2008 (9.0) provides TR1 tuple in a 323 MB Feature Pack download, which we cannot assume the user has. QNX's QCC compiler is a modified GCC but it doesn't support TR1 tuple. libc++ only provides std::tuple, in C++11 mode, and it can be used with some compilers that define __GNUC__.
86395. Since the lock is being released the owner_ field should no longer be considered valid. We don't protect writing to has_owner_ here, as it's the caller's responsibility to ensure that the current thread holds the mutex when this is called.
86396. NOLINT GTEST_OS_WINDOWS
86397. Ensures that there is at least one operator<< in the global namespace. See Message& operator<<(...) below for why.
86398. **comment:** String - an abstract class holding static string utilities.
label: code-design
86399. RemoveFileName returns the directory path with the filename removed. Example: FilePath("path/to/file").RemoveFileName() returns "path/to/". If the FilePath is "a_file" or "/a_file", RemoveFileName returns FilePath("./") or, on Windows, FilePath("\\"). If the filepath does not have a file, like "just/a/dir/", it returns the FilePath unmodified. On Windows platform, '\' is the path separator, otherwise it is '/'.
86400. Enough has been printed.
86401. The relation between an NativeArray object (see below) and the native array it represents. We use 2 different structs to allow non-copyable types to be used, as long as RelationToSourceReference() is passed.
86402. Returns the text streamed into this AssertionResult. Test assertions use it when they fail (i.e., the predicate's outcome doesn't match the assertion's expectation). When nothing has been streamed into the object, returns an empty string.
86403. Overload for wchar_t type. Prints a wchar_t as a symbol if it is printable or as its internal code otherwise and also as its decimal code (except for L'0'). The L'0' char is printed as "L'\0'". The decimal code is printed as signed integer when wchar_t is implemented by the compiler as a signed type and is printed as an unsigned integer when wchar_t is implemented as an unsigned type.
86404. **comment:** We don't want to require the users to write TemplatesN<...> directly, as that would require them to count the length. Templates<...> is much easier to write, but generates horrible messages when there is a compiler error, as gcc insists on printing out each template argument, even if it has the default value (this means Templates<list> will appear as Templates<list, NoneT, NoneT, ..., NoneT> in the compiler errors). Our solution is to combine the best part of the two approaches: a user would write Templates<T1, ..., TN>, and Google Test will translate that to TemplatesN<T1, ..., TN> internally to make error messages readable. The translation is done by the 'type' member of the Templates template.
label: code-design
86405. If the compiler is not GCC 4.0+, we assume the user is using a spec-conforming TR1 implementation. IWYU pragma: export // NOLINT
 GTEST_USE_OWN_TR1_TUPLE
86406. Macros for defining flags.
86407. Prints TestPartResult object.
86408. test_part_result
86409. The Mutex class can only be used for mutexes created at runtime. It shares its API with MutexBase otherwise.
86410. Helper function for printing a tuple. T must be instantiated with a tuple type.
86411. namespace posix
86412. Utilities for char.
86413. Depending on the platform, different string classes are available. On Linux, in addition to ::std::string, Google also makes use of class ::string, which has the same interface as ::std::string, but has a different implementation. You can define GTEST_HAS_GLOBAL_STRING to 1 to indicate that ::string is available AND is a distinct type to ::std::string, or define it to 0 to indicate otherwise. If ::std::string and ::string are the same class on your platform due to aliasing, you should define GTEST_HAS_GLOBAL_STRING to 0. If you do not define GTEST_HAS_GLOBAL_STRING, it is defined heuristically.
86414. We disallow copying UnitTest.
86415. This macro is used for implementing macros such as EXPECT_DEATH_IF_SUPPORTED and ASSERT_DEATH_IF_SUPPORTED on systems where death tests are not supported. Those macros must compile on such systems iff EXPECT_DEATH and ASSERT_DEATH compile with the same parameters on systems that support death tests. This allows one to write such a macro on a system that does not support death tests and be sure that it will compile on a death-test supporting system. Parameters: statement - A statement that a macro such as EXPECT_DEATH would test for program termination. This macro has to make sure this statement is compiled but not executed, to ensure that EXPECT_DEATH_IF_SUPPORTED compiles with a certain parameter iff EXPECT_DEATH compiles with it. regex - A regex that a macro such as EXPECT_DEATH would use to test the output of statement. This parameter has to be compiled but not evaluated by this macro, to ensure that this macro only accepts expressions that a macro such as EXPECT_DEATH would accept. terminator - Must be an empty statement for EXPECT_DEATH_IF_SUPPORTED and a return statement for ASSERT_DEATH_IF_SUPPORTED. This ensures that ASSERT_DEATH_IF_SUPPORTED will not compile inside functions where ASSERT_DEATH doesn't compile. The branch that has an always false condition is used to ensure that statement and regex are compiled (and thus syntactically correct) but never executed. The unreachable code macro protects the terminator statement from generating an 'unreachable code' warning in case statement unconditionally returns or throws. The Message constructor at the end allows the syntax of streaming additional messages into the macro, for compilational compatibility with EXPECT_DEATH/ASSERT_DEATH.
86416. Prints a value using the type inferred by the compiler. The difference between this and UniversalTersePrint() is that for a (const) char pointer, this prints both the pointer and the NUL-terminated string.
86417. Define macro GTEST_DONT_DEFINE_ASSERT_XY to 1 to omit the definition of ASSERT_XY(), which clashes with some users' own code.
86418. GTEST_HASH_CXXABI_H
86419. Generates values from a range of two comparable values. Can be used to generate sequences of user-defined types that implement operator+() and operator<(). This class is used in the Range() function.
86420. t
86421. Two overloaded helpers for checking at compile time whether an expression is a null pointer literal (i.e. NULL or any 0-valued compile-time integral constant). Their return values have different sizes, so we can use sizeof() to test which version is picked by the compiler. These helpers have no implementations, as we only need their signatures. Given IsNullLiteralHelper(x), the compiler will pick the first version if x can be implicitly converted to Secret*, and pick the second version otherwise. Since Secret is a secret and incomplete type, the only expression a user can write that has type Secret* is a null pointer literal. Therefore, we know that x is a null pointer literal if and only if the first version is picked by the compiler.
86422. Returns the current OS stack trace as an std::string. The maximum number of stack frames to be included is specified by the gtest_stack_trace_depth flag. The skip_count parameter specifies the number of top frames to be skipped, which doesn't count against the number of frames to be included. For example, if Foo() calls Bar(), which in turn calls GetCurrentOsStackTraceExceptTop(..., 1), Foo() will be included in the trace but Bar() and GetCurrentOsStackTraceExceptTop() won't.
86423. **comment:** MSVC's and C++Builder's implementations of the STL use the _HAS_EXCEPTIONS macro to enable exceptions, so we'll do the same. Assumes that exceptions are enabled by default.
label: code-design
86424. A concrete DeathTestFactory implementation for normal use.
86425. Text representation of the value parameter, or NULL if this is not a value-parameterized test.
86426. The convenience class for users who need to override just one or two methods and are not concerned that a possible change to a signature of the methods they override will not be caught during the build. For comments about each method please see the definition of TestEventListener above.
86427. Holds test properties recorded during execution of SetUpTestCase and TearDownTestCase.
86428. GTEST_HAS_GLOBAL_STRING
86429. This namespace MUST NOT BE NESTED IN ::testing, or the name look-up magic needed for implementing UniversalPrinter won't work.
86430. **comment:** clang defines __EXCEPTIONS iff exceptions are enabled before clang 220714, but iff cleanups are enabled after that. In Obj-C++ files, there can be cleanups for ObjC exceptions which also need cleanups, even if C++ exceptions are disabled. clang has __has_feature(cxx_exceptions) which checks for C++

exceptions starting at clang r206352, but which checked for cleanups prior to that. To reliably check for C++ exception availability with clang, check for `__EXCEPTIONS && __has_feature(cxx_exceptions)`.

label: code-design

86431. `_MSC_VER`

86432. Override this to define how to tear down the environment.

86433. `GTEST_INCLUDE_GTEST_GTEST_PRINTERS_H_`

86434. Appends the contents of message to message_.

86435. This template class serves as a compile-time function from size to type. It maps a size in bytes to a primitive type with that size. e.g. `TypeWithSize<4>::UInt` is typedef-ed to be unsigned int (unsigned integer made up of 4 bytes). Such functionality should belong to STL, but I cannot find it there. Google Test uses this class in the implementation of floating-point comparison. For now it only handles UInt (unsigned int) as that's all Google Test needs. Other types can be easily added in the future if need arises.

86436. Uses a GTestFlagSaver to save and restore all Google Test flags.

86437. Parses a bool/Int32/string from the environment variable corresponding to the given Google Test flag.

86438. Constructs a FloatingPoint from a raw floating-point number. On an Intel CPU, passing a non-normalized NAN (Not a Number) around may change its bits, although the new value is guaranteed to be also a NAN. Therefore, don't expect this constructor to preserve the bits in x when x is a NAN.

86439. Gets the (immutable) vector of TestInfos in this TestCase.

86440. Advances iterator to point to the next element provided by the generator. The caller is responsible for not calling Advance() on an iterator equal to BaseGenerator()->End().

86441. When the compiler sees expression `IsContainerTest<C>(0)`, if C is an STL-style container class, the first overload of IsContainerTest will be viable (since both `C::iterator*` and `C::const_iterator*` are valid types and `NULL` can be implicitly converted to them). It will be picked over the second overload as 'int' is a perfect match for the type of argument 0. If `C::iterator` or `C::const_iterator` is not a valid type, the first overload is not viable, and the second overload will be picked. Therefore, we can determine whether C is a container class by checking the type of `IsContainerTest<C>(0)`. The value of the expression is insignificant. Note that we look for both `C::iterator` and `C::const_iterator`. The reason is that C++ injects the name of a class as a member of the class itself (e.g. you can refer to class iterator as either 'iterator' or 'iterator::iterator'). If we look for `C::iterator` only, for example, we would mistakenly think that a class named iterator is an STL container. Also note that the simpler approach of overloading `IsContainerTest(typename C::const_iterator*)` and `IsContainerTest(...)` doesn't work with Visual Age C++ and Sun C++.

86442. **comment:** Result of an assertion. Represents a failure message. Represents a test. Information about a test. Result of a test part. A collection of test cases.

label: test

86443. `GTEST_n_TYPENAMES_(T)` declares a list of n typenames.

86444. Implements the helper function for `{ASSERT|EXPECT}_NE`

86445. `INSTANTIATE_TEST_CASE_P` macro uses AddGenerator() to record information about a generator.

86446. Gets the line in the source file where the test part took place, or -1 if it's unknown.

86447. 6.1.3.3 Tuple helper classes.

86448. Listener responsible for the creation of the XML output file.

86449. class `CartesianProductGenerator5`

86450. `EXPECT_DEATH_IF_SUPPORTED(statement, regex)` and `ASSERT_DEATH_IF_SUPPORTED(statement, regex)` expand to real death tests if death tests are supported; otherwise they just issue a warning. This is useful when you are combining death test assertions with normal test assertions in one test.

86451. Overloads for other simple built-in types.

86452. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Expands to the name of the typedef for the type parameters of the given test case.

86453. Implementation details of `GTEST_COMPILE_ASSERT_`: (In C++11, we simply use `static_assert` instead of the following) - `GTEST_COMPILE_ASSERT_` works by defining an array type that has -1 elements (and thus is invalid) when the expression is false. - The simpler definition `#define`

`GTEST_COMPILE_ASSERT_(expr, msg)` `typedef char msg[(expr) ? 1 : -1]` does not work, as gcc supports variable-length arrays whose sizes are determined at run-time (this is gcc's extension and not part of the C++ standard). As a result, gcc fails to reject the following code with the simple definition: `int foo;`
`GTEST_COMPILE_ASSERT_(foo, msg); // not supposed to compile as foo is // not a compile-time constant.` - By using the type `CompileAssert<(bool(expr))>`, we ensures that expr is a compile-time constant. (Template arguments must be determined at compile-time.) - The outer parentheses in `CompileAssert<(bool(expr))>` are necessary to work around a bug in gcc 3.4.4 and 4.0.1. If we had written `CompileAssert<bool(expr)>` instead, these compilers will refuse to compile `GTEST_COMPILE_ASSERT_(5 > 0, some_message);` (They seem to think the ">" in "5 > 0" marks the end of the template argument list.) - The array size is `(bool(expr) ? 1 : -1)`, instead of simply `((expr) ? 1 : -1)`. This is to avoid running into a bug in MS VC 7.1, which causes `((0.0) ? 1 : -1)` to incorrectly evaluate to 1.

86454. Elapsed time, in milliseconds.

86455. We used to have a second template parameter instead of `Secret*`. That template parameter would deduce to 'long', making this a better match than the first overload even without the first overload's `EnableIf`. Unfortunately, gcc with -Wconversion-null warns when "passing NULL to non-pointer argument" (even a deduced integral argument), so the old implementation caused warnings in user code.

86456. The actual list of listeners.

86457. Define this macro to 1 to omit the definition of `SUCCEED()`, which is a generic name and clashes with some other libraries.

86458. The `TypeList` template makes it possible to use either a single type or a `Types<...>` list in `TYPED_TEST_CASE()` and `INSTANTIATE_TYPED_TEST_CASE_P()`.

86459. Gets the number of disabled tests.

86460. Constructs an empty Message.

86461. Gets the singleton `UnitTest` object. The first time this method is called, a `UnitTest` object is constructed and returned. Consecutive calls will return the same object.

86462. Holds a value of T. Can be deleted via its base class without the caller knowing the type of T.

86463. Functions deprecated by MSVC 8.0.

86464. This overload prints a (const) `wchar_t` array compactly.

86465. For static mutexes, we rely on these members being initialized to zeros by the linker.

86466. Gets the summary of the failure message by omitting the stack trace in it.

86467. `GTEST_INCLUDE_GTEST_INTERNAL_GTEST_STRING_H_` Copyright 2008, Google Inc. All rights reserved. Author: keith.ray@gmail.com (Keith Ray) Google Test filepath utilities This header file declares classes and functions used internally by Google Test. They are subject to change without notice. This file is #included in `<gtest/internal/gtest-internal.h>`. Do not include this header file separately!

86468. The empty type list.

86469. Returns true iff the given string ends with the given suffix, ignoring case. Any string is considered to end with an empty suffix.

86470. Holds a value of type T.

86471. Clears the object.

86472. These fields are immutable properties of the test. Test case name Test name Name of the parameter type, or NULL if this is not a typed or a type-parameterized test.

86473. Internal macro for implementing `{EXPECT|ASSERT}_PRED_FORMAT1`. Don't use this in your code.

86474. Tersely prints the first N fields of a tuple to a string vector, one element for each field.

86475. This macro is for implementing `ASSERT_DEATH*`, `EXPECT_DEATH*`, `ASSERT_EXIT*`, and `EXPECT_EXIT*`.

86476. The line in the source file where the test part took place, or -1 if the line number is unknown.

86477. We must report iterators equal if they both point beyond their respective ranges. That can happen in a variety of fashions, so we have to consult AtEnd().
86478. Older versions of MSVC don't have __pragma.
86479. **comment:** Returns true iff this number is at most kMaxUlps ULP's away from rhs. In particular, this function: - returns false if either number is (or both are) NAN.
- treats really large numbers as almost equal to infinity. - thinks +0.0 and -0.0 are 0 DLP's apart.
label: code-design
86480. !GTEST_OS_WINDOWS
86481. The explicit constructor call suppresses a false warning emitted by gcc when supplied with the -Wextra option.
86482. **comment:** Shuffles the tests in this test case.
label: test
86483. Like ASSERT_EXIT, but continues on to successive tests in the test case, if any:
86484. Returns true iff the test part passed.
86485. dummy
86486. Adds a test property to the list. The property is validated and may add a non-fatal failure if invalid (e.g., if it conflicts with reserved key names). If a property is already recorded for the same key, the value will be updated, rather than storing multiple values for the same key. xml_element specifies the element for which the property is being recorded and is used for validation.
86487. Interface for iterating over elements provided by an implementation of ParamGeneratorInterface<T>.
86488. The d'tor is virtual as we need to subclass Environment.
86489. Since T has no << operator or PrintTo() but can be implicitly converted to BiggestInt, we print it as a BiggestInt. Most likely T is an enum type (either named or unnamed), in which case printing it as an integer is the desired behavior. In case T is not an enum, printing it as an integer is the best we can do given that it has no user-defined printer.
86490. **comment:** Define this macro to 1 to omit the definition of TEST(), which is a generic name and clashes with some other libraries.
label: code-design
86491. Implements Boolean test assertions such as EXPECT_TRUE. expression can be either a boolean expression or an AssertionResult. text is a textual representation of expression as it was passed into the EXPECT_TRUE.
86492. **comment:** We don't want to require the users to write TypesN<...> directly, as that would require them to count the length. Types<...> is much easier to write, but generates horrible messages when there is a compiler error, as gcc insists on printing out each template argument, even if it has the default value (this means Types<int> will appear as Types<int, None, None, ..., None> in the compiler errors). Our solution is to combine the best part of the two approaches: a user would write Types<T1, ..., TN>, and Google Test will translate that to TypesN<T1, ..., TN> internally to make error messages readable. The translation is done by the 'type' member of the Types template.
label: code-design
86493. By default, ::testing::internal::PrintTo() is used for printing the value. Thanks to Koenig look-up, if T is a class and has its own PrintTo() function defined in its namespace, that function will be visible here. Since it is more specific than the generic ones in ::testing::internal, it will be picked by the compiler in the following statement - exactly what we want.
86494. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_INTERNAL_H_
86495. Appends the given TestPartResult to the array.
86496. Returns the maximum representable finite floating-point number.
86497. Clones the iterator object. Used for implementing copy semantics of ParamIterator<T>.
86498. namespace testing_internal
86499. Stores result of the assertion predicate.
86500. Clears the results of all tests in this test case.
86501. Fired after the test ends.
86502. Returns true if FilePath describes something in the file-system, either a file, directory, or whatever, and that something exists.
86503. Makes a failed assertion result.
86504. GTEST_USE_OWN_TR1_TUPLE
86505. The underlying pthread mutex. has_owner_ indicates whether the owner_ field below contains a valid thread ID and is therefore safe to inspect (e.g., to use in pthread_equal()). All accesses to the owner_ field should be protected by a check of this field. An alternative might be to memset() owner_ to all zeros, but there's no guarantee that a zero'd pthread_t is necessarily invalid or even different from pthread_self().
86506. class CartesianProductHolder10
86507. The key supplied by the user.
86508. Returns true iff the test case passed.
86509. Internal macro for implementing {EXPECT|ASSERT}_PRED3. Don't use this in your code.
86510. ChDir(), FReopen(), FDOpen(), Read(), Write(), Close(), and StrError() aren't needed on Windows CE at this time and thus not defined there.
86511. TypeWithoutFormatter<T, kTypeKind>::PrintValue(value, os) is called by the universal printer to print a value of type T when neither operator<< nor PrintTo() is defined for T, where kTypeKind is the "kind" of T as defined by enum TypeKind.
86512. **comment:** A ScopedTrace object does its job in its c'tor and d'tor. Therefore it doesn't need to be used otherwise.
label: code-design
86513. GTEST_HAS_STD_WSTRING
86514. The vector of TestProperties
86515. BOOST_HAS_TR1_TUPLE
86516. See the comments in Message& operator <<(const T&) above for why we need this using statement.
86517. **comment:** Returns a human-readable outcome message regarding the outcome of the last death test.
label: code-design
86518. Copyright 2008, Google Inc. All rights reserved. Authors: vladl@google.com (Vlad Losev) Macros and functions for implementing parameterized tests in Google C++ Testing Framework (Google Test) This file is generated by a SCRIPT. DO NOT EDIT BY HAND!
86519. Returns the TestInfo object for the test that's currently running, or NULL if no test is running.
86520. _HAS_EXCEPTIONS
86521. Returns the optimal edits to go from 'left' to 'right'. All edits cost the same, with replace having lower priority than add/remove. Simple implementation of the Wagner-Fischer algorithm. See http://en.wikipedia.org/wiki/Wagner-Fischer_algorithm
86522. Copy constructor.
86523. Compiling in at least C++11 mode.
86524. Range() returns generators providing sequences of values in a range. Synopsis: Range(start, end) - returns a generator producing a sequence of values {start, start+1, start+2, ...}. Range(start, end, step) - returns a generator producing a sequence of values {start, start+step, start+step+step, ...}. Notes: * The generated sequences never include end. For example, Range(1, 5) returns a generator producing a sequence {1, 2, 3, 4}. Range(1, 9, 2) returns a generator producing {1, 3, 5, 7}. * start and end must have the same type. That type may be any integral or floating-point type or a user defined type satisfying these conditions: * It must be assignable (have operator=() defined). * It must have operator+(operator+(int-compatible type) for two-operand version). * It must have operator<() defined. Elements in the resulting sequences will also have that type. * Condition start < end must be satisfied in order for resulting sequences to contain any elements.
86525. If the type list contains only one type, you can write that type directly without Types<...>: TYPED_TEST_CASE(FooTest, int);

86526. Returns true iff the assertion succeeded. NOLINT
86527. Known limitations: we don't support passing an std::tr1::reference_wrapper<T> to make_tuple(). And we don't implement tie().
86528. A handy wrapper for AddRef.
86529. const_it
86530. This template class represents an IEEE floating-point number (either single-precision or double-precision, depending on the template parameters). The purpose of this class is to do more sophisticated number comparison. (Due to round-off error, etc, it's very unlikely that two floating-points will be equal exactly. Hence a naive comparison by the == operation often doesn't work.) Format of IEEE floating-point: The most-significant bit being the leftmost, an IEEE floating-point looks like sign_bit exponent_bits fraction_bits Here, sign_bit is a single bit that designates the sign of the number. For float, there are 8 exponent bits and 23 fraction bits. For double, there are 11 exponent bits and 52 fraction bits. More details can be found at http://en.wikipedia.org/wiki/IEEE_floating-point_standard. Template parameter: RawType: the raw floating-point type (either float or double)
86531. Returns the i-th test property. i can range from 0 to test_property_count() - 1. If i is not in that range, aborts the program.
86532. A copy constructor is required by the Standard to initialize object references from r-values.
86533. class TestResult
86534. pthread_key_create() requires DeleteThreadLocalValue() to have C-linkage. Therefore it cannot be templated to access ThreadLocal<T>. Hence the need for class ThreadLocalValueHolderBase.
86535. Complain about incorrect usage of Google Test facilities and terminate the program since we cannot guarantee correct test case setup and tear-down in this case.
86536. A function level attribute to disable ThreadSanitizer instrumentation.
86537. **comment:** When you need to test the private or protected members of a class, use the FRIEND_TEST macro to declare your tests as friends of the class. For example: class MyClass { private: void MyMethod(); FRIEND_TEST(MyClassTest, MyMethod); }; class MyClassTest : public testing::Test { // ... }; TEST_F(MyClassTest, MyMethod) { // Can call MyClass::MyMethod() here. }
- label:** test
86538. On Android, <regex.h> is only available starting with Gingerbread.
86539. By default, we assume that stream redirection is supported on all platforms except known mobile ones.
86540. Prints the address of the value. We use reinterpret_cast here as static_cast doesn't compile when T is a function type.
86541. When building against STLport with the Android NDK and with -frtti -fno-exceptions, the build fails at link time with undefined references to __cxa_bad_typeid. Note sure if STL or toolchain bug, so disable RTTI when detected.
86542. Definitions in the 'internal' and 'internal2' name spaces are subject to change without notice. DO NOT USE THEM IN USER CODE!
86543. The variables defined in the type-parameterized test macros are static as typically these macros are used in a .h file that can be #included in multiple translation units linked together.
86544. IsSubstring() and IsNotSubstring() are intended to be used as the first argument to {EXPECT,ASSERT}_PRED_FORMAT2(), not by themselves. They check whether needle is a substring of haystack (NULL is considered a substring of itself only), and return an appropriate error message when they fail. The {needle,haystack}_expr arguments are the stringified expressions that generated the two real arguments.
86545. Internal macro for implementing {EXPECT|ASSERT}_PRED_FORMAT3. Don't use this in your code.
86546. Adapts a native array to a read-only STL-style container. Instead of the complete STL container concept, this adaptor only implements members useful for Google Mock's container matchers. New members should be added as needed. To simplify the implementation, we only support Element being a raw type (i.e. having no top-level const or reference modifier). It's the client's responsibility to satisfy this requirement. Element can be an array type itself (hence multi-dimensional arrays are supported).
86547. Non-static methods
86548. A handy wrapper for ByRef.
86549. Runs SetUpTestCase() for this TestCase. This wrapper is needed for catching exceptions thrown from SetUpTestCase().
86550. NOLINT NOLINT NOLINT NOLINT
86551. **comment:** This helper reduces code bloat. If we instead put its logic inside the previous ArrayEq() function, arrays with different sizes would lead to different copies of the template code.
- label:** code-design
86552. Overload for ::std::tr1::tuple. Needed for printing function arguments, which are packed as tuples.
86553. Running count of death tests.
86554. Reinterprets a bit pattern as a floating-point number. This function is needed to test the AlmostEquals() method.
86555. Determines whether Google Test's own tr1 tuple implementation should be used.
86556. class CartesianProductHolder3
86557. class CartesianProductGenerator8
86558. for isspace, etc for ptrdiff_t
86559. scripts/fuse_gtest.py depends on gtest's own header being #included *unconditionally*. Therefore these #includes cannot be moved inside #if GTEST_HAS_PARAM_TEST. Copyright 2003 Google Inc. All rights reserved. Authors: Dan Egnor (egnor@google.com) A "smart" pointer type with reference tracking. Every pointer to a particular object is kept on a circular linked list. When the last pointer to an object is destroyed or reassigned, the object is deleted. Used properly, this deletes the object when the last reference goes away. There are several caveats: - Like all reference counting schemes, cycles lead to leaks. - Each smart pointer is actually two pointers (8 bytes instead of 4). - Every time a pointer is assigned, the entire list of pointers to that object is traversed. This class is therefore NOT SUITABLE when there will often be more than two or three pointers to a particular object. - References are only tracked as long as linked_ptr<> objects are copied. If a linked_ptr<> is converted to a raw pointer and back, BAD THINGS will happen (double deletion). A good use of this class is storing object references in STL containers. You can safely put linked_ptr<> in a vector<>. Other uses may not be as good. Note: If you use an incomplete type with linked_ptr<>, the class *containing* linked_ptr<> must have a constructor and destructor (even if they do nothing!). Bill Gibbons suggested we use something like this. Thread Safety: Unlike other linked_ptr implementations, in this implementation a linked_ptr object is thread-safe in the sense that: - it's safe to copy linked_ptr objects concurrently, - it's safe to copy *from* a linked_ptr and read its underlying raw pointer (e.g. via get()) concurrently, and - it's safe to write to two linked_ptrs that point to the same shared object concurrently. TODO(wan@google.com): rename this to safe_linked_ptr to avoid confusion with normal linked_ptr.
86560. Helper class for testing Google Test's multi-threading constructs. To use it, write: void ThreadFunc(int param) { /* Do things with param */ } Notification thread_can_start; ... // The thread_can_start parameter is optional; you can supply NULL. ThreadWithParam<int> thread(&ThreadFunc, 5, &thread_can_start); thread_can_start.Notify(); These classes are only for testing Google Test's own constructs. Do not use them in user tests, either directly or indirectly.
86561. C++11 specifies that <tuple> provides std::tuple. Some platforms still might not have it, however.
86562. No value parameter.
86563. C'tor. TestPartResult does NOT have a default constructor. Always use this constructor (with parameters) to create a TestPartResult object.
86564. **comment:** Stores the message describing the condition in case the expectation construct is not satisfied with the predicate's outcome. Referenced via a pointer to avoid taking too much stack frame space with test assertions.
- label:** code-design
86565. Keeps pairs of <Instantiation name, Sequence generator creation function> received from INSTANTIATE_TEST_CASE_P macros.
86566. Prints a value tersely: for a reference type, the referenced value (but not the address) is printed; for a (const) char pointer, the NUL-terminated string (but not the pointer) is printed.
86567. We must report iterator past the end of the range when either of the component iterators has reached the end of its range.
86568. Swap the contents of this AssertionResult with other.

86569. **comment:** A UnitTest consists of a vector of TestCases. This is a singleton class. The only instance of UnitTest is created when UnitTest::GetInstance() is first called. This instance is never deleted. UnitTest is not copyable. This class is thread-safe as long as the methods are called according to their specification.

label: code-design

86570. Removes the reference from a type if it is a reference type, otherwise leaves it unchanged. This is the same as tr1::remove_reference, which is not widely available yet.

86571. GCC 4.0+ implements tr1/tuple in the <tr1/tuple> header. This does not conform to the TR1 spec, which requires the header to be <tuple>.

86572. We only implement == and !=, as we don't have a need for the rest yet.

86573. Given two numbers in the sign-and-magnitude representation, returns the distance between them as an unsigned number.

86574. The following family of struct and struct templates are used to represent template lists. In particular, TemplatesN<T1, T2, ..., TN> represents a list of N templates (T1, T2, ..., and TN). Except for Templates0, every struct in the family has two member types: Head for the selector of the first template in the list, and Tail for the rest of the list.

86575. **comment:** Here's what happens when an ASSERT_DEATH* or EXPECT_DEATH* is executed: 1. It generates a warning if there is more than one active thread. This is because it's safe to fork() or clone() only when there is a single thread. 2. The parent process clone(s) a sub-process and runs the death test in it; the sub-process exits with code 0 at the end of the death test, if it hasn't exited already. 3. The parent process waits for the sub-process to terminate. 4. The parent process checks the exit code and error message of the sub-process. Examples: ASSERT_DEATH(server.SendMessage(56, "Hello"), "Invalid port number"); for (int i = 0; i < 5; i++) { EXPECT_DEATH(server.ProcessRequest(i), "Invalid request * in ProcessRequest()") << "Failed to die on request " << i; } ASSERT_EXIT(server.ExitNow(), ::testing::ExitedWithCode(0), "Exiting"); bool KilledBySIGHUP(int exit_code) { return WIFSIGNALED(exit_code) && WTERMSIG(exit_code) == SIGHUP; } ASSERT_EXIT(client.HangUpServer(), KilledBySIGHUP, "Hanging up!"); On the regular expressions used in death tests: On POSIX-compliant systems (*nix), we use the <regex.h> library, which uses the POSIX extended regex syntax. On other platforms (e.g. Windows), we only support a simple regex syntax implemented as part of Google Test. This limited implementation should be enough most of the time when writing death tests; though it lacks many features you can find in PCRE or POSIX extended regex syntax. For example, we don't support union ("x|y"), grouping ("(xy)"), brackets ("[xy]"), and repetition count ("x{5,7}"), among others. Below is the syntax that we do support. We chose it to be a subset of both PCRE and POSIX extended regex, so it's easy to learn wherever you come from. In the following: 'A' denotes a literal character, period (.), or a single \ escape sequence; 'x' and 'y' denote regular expressions; 'm' and 'n' are for natural numbers. c matches any literal character c \d matches any decimal digit \D matches any character that's not a decimal digit \f matches f \n matches \r \n matches \r \s matches any ASCII whitespace, including \n \S matches any character that's not a whitespace \t matches \t \w matches \w \w matches any letter, _ or decimal digit \W matches any character that \w doesn't match \c matches any literal character c, which must be a punctuation . matches any single character except \n A? matches 0 or 1 occurrences of A A* matches 0 or many occurrences of A A+ matches 1 or many occurrences of A ^ matches the beginning of a string (not that of each line) \$ matches the end of a string (not that of each line) xy matches x followed by y If you accidentally use PCRE or POSIX extended regex features not implemented by us, you will get a run-time failure. In that case, please try to rewrite your regular expression within the above syntax. This implementation is *not* meant to be as highly tuned or robust as a compiled regex library, but should perform well enough for a death test, which already incurs significant overhead by launching a child process. Known caveats: A "threadsafe" style death test obtains the path to the test program from argv[0] and re-executes it in the sub-process. For simplicity, the current implementation doesn't search the PATH when launching the sub-process. This means that the user must invoke the test program via a path that contains at least one path separator (e.g. path/to/foo_test and /absolute/path/to/bar_test are fine, but foo_test is not). This is rarely a problem as people usually don't put the test binary directory in PATH.

TODO(wan@google.com): make thread-safe death tests search the PATH.

Author: wan@google.com (Zhangyong Wan)

86577. **comment:** A macro to disallow operator= This should be used in the private: declarations for a class.

label: code-design

86578. **comment:** Use this annotation at the end of a struct/class definition to prevent the compiler from optimizing away instances that are never used. This is useful when all interesting logic happens inside the c'tor and / or d'tor. Example: struct Foo { Foo() { ... } } GTEST_ATTRIBUTE_UNUSED_; Also use it after a variable or parameter declaration to tell the compiler the variable/parameter does not have to be used.

label: code-design

86579. Create a diff of the input strings in Unified diff format.

86580. Many linked_ptr operations may change p.link_ for some linked_ptr variable p in the same circle as this object. Therefore we need to prevent two such operations from occurring concurrently. Note that different types of linked_ptr objects can coexist in a circle (e.g. linked_ptr<Base>, linked_ptr<Derived1>, and linked_ptr<Derived2>). Therefore we must use a single mutex to protect all linked_ptr objects. This can create serious contention in production code, but is acceptable in a testing framework.

86581. Override this to define how to set up the environment.

86582. Name of the test case.

86583. Registers thread_local_instance as having value on the current thread. Returns a value that can be used to identify the thread from other threads.

86584. **comment:** How many ULP's (Units in the Last Place) we want to tolerate when comparing two numbers. The larger the value, the more error we allow. A 0 value means that two numbers must be exactly the same to be considered equal. The maximum error of a single floating-point operation is 0.5 units in the last place. On Intel CPU's, all floating-point calculations are done with 80-bit precision, while double has 64 bits. Therefore, 4 should be enough for ordinary use. See the following article for more details on ULP: <http://randomascii.wordpress.com/2012/02/25/comparing-floating-point-numbers-2012-edition/>

label: code-design

86585. class CartesianProductHolder2

86586. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Expands to the namespace name that the type-parameterized tests for the given type-parameterized test case are defined in. The exact name of the namespace is subject to change without notice.

86587. Dereferences the current iterator and provides (read-only) access to the pointed value. It is the caller's responsibility not to call Current() on an iterator equal to BaseGenerator()->End(). Used for implementing ParamGenerator<T>::operator*().

86588. Determines whether clone(2) is supported. Usually it will only be available on Linux, excluding Linux on the Itanium architecture. Also see <http://linux.die.net/man/2/clone>.

86589. Formats a comparison assertion (e.g. ASSERT_EQ, EXPECT_LT, and etc) operand to be used in a failure message. The type (but not value) of the other operand may affect the format. This allows us to print a char* as a raw pointer when it is compared against another char* or void*, and print it as a C string when it is compared against an std::string object, for example. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86590. Implements typed tests.

86591. GTEST_HAS_POSIX_REGEX

86592. Allows the user to #include <tr1/functional> if he chooses to.

86593. We'll hold the text streamed to this object here.

86594. The user didn't tell us whether ::string is available, so we need to figure it out.

86595. **comment:** Used to print a value that is not an STL-style container when the user doesn't define PrintTo() for it.

label: code-design

86596. <regex.h> may not be available on this platform. Use our own simple regex implementation instead.

86597. Constructs an RE from a string. NOLINT

86598. The testing::internal::posix namespace holds wrappers for common POSIX functions. These wrappers hide the differences between Windows/MSVC and POSIX systems. Since some compilers define these standard functions as macros, the wrapper cannot have the same name as the wrapped function.

86599. GTESTUSES_SIMPLE_RE

86600. Helper class for testing Google Test's multi-threading constructs.

86601. **comment:** Replaces multiple consecutive separators with a single separator. For example, "bar///foo" becomes "bar/foo". Does not eliminate other redundancies that might be in a pathname involving "." or "..". A pathname with multiple consecutive separators may occur either through user error or as a result of some scripts or APIs that generate a pathname with a trailing separator. On other platforms the same API or script may NOT generate a pathname with a trailing "/". Then elsewhere that pathname may have another "/" and pathname components added to it, without checking for the separator already being there. The script language and operating system may allow paths like "foo/bar" but some of the functions in FilePath will not handle that correctly. In particular, RemoveTrailingPathSeparator() only removes one separator, and it is called in CreateDirectoriesRecursively() assuming that it will change a pathname from directory syntax (trailing separator) to filename syntax. On Windows this method also replaces the alternate path separator '/' with the primary path separator '\\', so that for example "bar\\\\\\foo" becomes "bar\\foo".

label: code-design

86602. GTEST_ELLIPSIS_NEEDS_POD_

86603. Names of the flags (needed for parsing Google Test flags).

86604. Prints the given array, omitting some elements when there are too many.

86605. StaticAssertTypeEqHelper is used by StaticAssertTypeEq defined in gtest.h. This template is declared, but intentionally undefined.

86606. class CartesianProductHolder9

86607. Message assignment is a semantic trick to enable assertion streaming; see the GTEST_MESSAGE_ macro below.

86608. We disallow copying Tests.

86609. Gets the number of failed tests.

86610. gcc's implementation of typeid(T).name() mangles the type name, so we have to demangle it.

86611. Ask the compiler to never inline a given function.

86612. This implementation of scoped_ptr is PARTIAL - it only contains enough stuff to satisfy Google Test's need.

86613. GCC 4.4.6

86614. **comment:** MutexBase and Mutex implement mutex on pthreads-based platforms.

label: requirement

86615. Returns a newly created InternalRunDeathTestFlag object with fields initialized from the GTEST_FLAG(internal_run_death_test) flag if the flag is specified; otherwise returns NULL.

86616. Returns true if any test in this test case should run.

86617. Gets the user supplied value.

86618. Gets the number of all test cases.

86619. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Authors: wan@google.com (Zhanyong Wan), eefacm@gmail.com (Sean McAfee) The Google C++ Testing Framework (Google Test) This header file defines internal utilities needed for implementing death tests. They are subject to change without notice.

86620. Returns the exponent bits of this number.

86621. Returns true iff the test part non-fatally failed.

86622. **comment:** Gets the outcome of the test part.

label: test

86623. GTEST_HAS_PTHREAD

86624. Returns true if this test should run, that is if the test is not disabled (or it is disabled but the also_run_disabled_tests flag has been specified) and its full name matches the user-specified filter. Google Test allows the user to filter the tests by their full names. The full name of a test Bar in test case Foo is defined as "Foo.Bar". Only the tests that match the filter will run. A filter is a colon-separated list of glob (not regex) patterns, optionally followed by a '-' and a colon-separated list of negative patterns (tests to exclude). A test is run if it matches one of the positive patterns and does not match any of the negative patterns. For example, *A*:Foo.* is a filter that matches any string that contains the character 'A' or starts with "Foo".

86625. test_case

86626. Returns the standard listener responsible for the default console output. Can be removed from the listeners list to shut down default console output. Note that removing this object from the listener list with Release transfers its ownership to the caller and makes this function return NULL the next time.

86627. Determines whether RTTI is available.

86628. Tests that an exit code describes a normal exit with a given exit code.

86629. Fired after environment tear-down for each iteration of tests ends.

86630. Value-parameterized tests allow you to test your code with different parameters without writing multiple copies of the same test. Here is how you use value-parameterized tests:

86631. class ParameterizedTestCaseInfo

86632. Creates the test object, runs it, records its result, and then deletes it.

86633. UniversalPrinter<T>::Print(value, ostream_ptr) prints the given value to the given ostream. The caller must ensure that 'ostream_ptr' is not NULL, or the behavior is undefined. We define UniversalPrinter as a class template (as opposed to a function template), as we need to partially specialize it for reference types, which cannot be done with function templates.

86634. We cannot use UniversalPrint(value.first, os) here, as T1 may be a reference type. The same for printing value.second.

86635. This flag specifies the random number seed.

86636. Blacklist of patch releases of older branches:

86637. A helper class for creating scoped traces in user programs.

86638. Fired after a failed assertion or a SUCCEED() invocation.

86639. Returns true iff the current test has a non-fatal failure.

86640. A handy wrapper around RemoveConst that works when the argument T depends on template parameters.

86641. This is used internally by all instances of linked_ptr<T>. It needs to be a non-template class because different types of linked_ptr<T> can refer to the same object (linked_ptr<Superclass>(obj) vs linked_ptr<Subclass>(obj)). So, it needs to be possible for different types of linked_ptr to participate in the same circular linked list, so we need a single class type here. DO NOT USE THIS CLASS DIRECTLY YOURSELF. Use linked_ptr<T>.

86642. A function to convert T* into linked_ptr<T>. Doing e.g. make_linked_ptr(new FooBarBaz<type>(arg)) is a shorter notation for linked_ptr<FooBarBaz<type> > (new FooBarBaz<type>(arg))

86643. This macro is for implementing ASSERT/EXPECT_DEBUG_DEATH when compiled in NDEBUG mode. In this case we need the statements to be executed, the regex is ignored, and the macro must accept a streamed message even though the message is never printed.

86644. Downcasts the pointer of type Base to Derived. Derived must be a subclass of Base. The parameter MUST point to a class of type Derived, not any subclass of it. When RTTI is available, the function performs a runtime check to enforce this.

86645. T is not a function type. We just call << to print p, relying on ADL to pick up user-defined << for their pointer types, if any.

86646. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_PARAM_UTIL_GENERATED_H_

86647. **comment:** The 'Types' template argument below must have spaces around it since some compilers may choke on '>>' when passing a template instance (e.g. Types<int>)

label: code-design

86648. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. A class that enables one to stream messages to assertion macros

86649. Internal macro for implementing {EXPECT|ASSERT}_PRED2. Don't use this in your code.
86650. GTEST_HAS_DEATH_TEST
86651. We have to put the 'public' section after the 'private' section, or MSVC refuses to compile the code.
86652. Used to define __ANDROID_API__ matching the target NDK API level. NOLINT
86653. Notifies all threads created with this notification to start. Must be called from the controller thread.
86654. A copyable object representing the result of a test part (i.e. an assertion or an explicit FAIL(), ADD_FAILURE(), or SUCCESS()). Don't inherit from TestPartResult as its destructor is not virtual.
86655. Defines types for pointers to functions that set up and tear down a test case.
86656. __CYGWIN__
86657. FormatForComparison<ToPrint, OtherOperand>::Format(value) formats a value of type ToPrint that is an operand of a comparison assertion (e.g. ASSERT_EQ). OtherOperand is the type of the other operand in the comparison, and is used to help determine the best way to format the value. In particular, when the value is a C string (char pointer) and the other operand is an STL string object, we want to format the C string as a string, since we know it is compared by value with the string object. If the value is a char pointer but the other operand is not an STL string object, we don't know whether the pointer is supposed to point to a NUL-terminated string, and thus want to print it as a pointer to be safe. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
86658. Copyright 2005, Google Inc. All rights reserved. Author: vlad@google.com (Vlad Losev)
86666. NULL if not a type-parameterized test NULL if not a value-parameterized test
86667. The helper function for {ASSERT|EXPECT}_STREQ. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
86668. Returns true iff the test failed.
86669. **comment:** Increments the number of death tests encountered in this test so far.
- label:** test
86670. Integer types of known sizes.
86671. **comment:** When you upcast (that is, cast a pointer from type Foo to type SuperclassOfFoo), it's fine to use ImplicitCast_<>, since upcasts always succeed. When you downcast (that is, cast a pointer from type Foo to type SubclassOfFoo), static_cast_<> isn't safe, because how do you know the pointer is really of type SubclassOfFoo? It could be a bare Foo, or of type DifferentSubclassOfFoo. Thus, when you downcast, you should use this macro. In debug mode, we use dynamic_cast_<> to double-check the downcast is legal (we die if it's not). In normal mode, we do the efficient static_cast_<> instead. Thus, it's important to test in debug mode to make sure the cast is legal! This is the only place in the code we should use dynamic_cast_<>. In particular, you SHOULDN'T be using dynamic_cast_<> in order to do RTTI (eg code like this: if (dynamic_cast<Subclass1>(foo)) HandleASubclass1Object(foo); if (dynamic_cast<Subclass2>(foo)) HandleASubclass2Object(foo); You should design the code some other way not to need this. This relatively ugly name is intentional. It prevents clashes with similar functions users may have (e.g., down_cast). The internal namespace alone is not enough because the function can be found by ADL. use like this: DownCast_<T*>(foo); so we only accept pointers Ensures that To is a sub-type of From *. This test is here only for compile-time type checking, and has no overhead in an optimized build at run-time, as it will be optimized away completely.
- label:** code-design
86672. MS C++ compiler emits warning when a conditional expression is compile time constant. In some contexts this warning is false positive and needs to be suppressed. Use the following two macros in such cases: GTEST_INTENTIONAL_CONST_COND_PUSH_() while (true) { GTEST_INTENTIONAL_CONST_COND_POP_0 }
86673. Gets the number of all test cases that contain at least one test that should run.
86674. The default value for each thread.
86675. Returns the type ID of ::testing::Test. Always call this instead of GetTypeId< ::testing::Test>() to get the type ID of ::testing::Test, as the latter may give the wrong result due to a suspected linker bug when compiling Google Test as a Mac OS X framework.
86676. class CartesianProductGenerator4
86677. class CartesianProductHolder6
86678. We rely on kStaticMutex being 0 as it is to what the linker initializes type_ in static mutexes. critical_section_ will be initialized lazily in ThreadSafeLazyInit().
86679. Implements thread-local storage on pthreads-based systems.
86680. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Helper classes providing Combine() with polymorphic features. They allow casting CartesianProductGeneratorN<T> to ParamGenerator<U> if T is convertible to U.
86681. This flags control whether Google Test prints the elapsed time for each test.
86682. Only use C++11 library features if the library provides them.
86683. Macros that execute statement and check that it doesn't generate new fatal failures in the current thread. * {ASSERT|EXPECT}_NO_FATAL_FAILURE(statement); Examples: EXPECT_NO_FATAL_FAILURE(Process()); ASSERT_NO_FATAL_FAILURE(Process()) << "Process() failed";
86684. class CartesianProductGenerator7::Iterator
86685. Gets the time of the test program start, in ms from the start of the UNIX epoch.
86686. These predicate format functions work on floating-point values, and can be used in {ASSERT|EXPECT}_PRED_FORMAT2*(), e.g. EXPECT_PRED_FORMAT2(testing::DoubleLE, Foo(), 5.0);
86687. The user told us that ::std::string isn't available.
86688. In order to avoid having to include <windows.h>, use forward declaration assuming CRITICAL_SECTION is a typedef of _RTL_CRITICAL_SECTION. This assumption is verified by WindowsTypesTest.CRITICAL_SECTIONIs_RTL_CRITICAL_SECTION.
86689. Gets the vector of TestPartResults.

86690. **comment:** TODO(vlidl@google.com): Remove this after making sure no clients use it. Deprecated; please use message() instead.

label: code-design

86691. Some libraries overload << for STL containers. These overloads are defined in the global namespace instead of ::std. C++'s symbol lookup rule (i.e. Koenig lookup) says that these overloads are visible in either the std namespace or the global namespace, but not other namespaces, including the testing namespace which Google Test's Message class is in. To allow STL containers (and other types that has a << operator defined in the global namespace) to be used in Google Test assertions, testing::Message must access the custom << operator from the global namespace. With this using declaration, overloads of << defined in the global namespace and those visible via Koenig lookup are both exposed in this function.

86692. sam represents a positive number.

86693. A helper class that aborts a death test when it's deleted.

86694. A function level attribute to disable AddressSanitizer instrumentation.

86695. Used in the Values() function to provide polymorphic capabilities.

86696. Pointer to the function that tears down the test case.

86697. Name of the parameter type, or NULL if this is not a typed or a type-parameterized test.

86698. This flag controls whether Google Test includes Google Test internal stack frames in failure stack traces.

86699. Gets the summary of the failure message.

86700. Listener responsible for the standard result output.

86701. Import tuple and friends into the ::testing namespace. It is part of our interface, having them in ::testing allows us to change their types as needed.

86702. deprecated function

86703. Registers and returns a global test environment. When a test program is run, all global test environments will be set-up in the order they were registered. After all tests in the program have finished, all global test environments will be torn-down in the *reverse* order they were registered. The UnitTest object takes ownership of the given environment. This method can only be called from the main thread.

86704. Factory interface for death tests. May be mocked out for testing.

86705. Gets the content of the stringstream's buffer as an std::string. Each '\0' character in the buffer is replaced with "\0".

86706. **comment:** We need the following helper functions only for their types. They have no implementations.

label: code-design

86707. **comment:** This interface knows how to report a test part result.

label: test

86708. Sets the elapsed time.

86709. fd

86710. Returns true iff test failed.

86711. This prevents <boost/tr1/detail/config.hpp>, which defines BOOST_HAS_TR1_TUPLE, from being #included by Boost's <tuple>.

86712. A static mutex may be used before main() is entered. It may even be used before the dynamic initialization stage. Therefore we must be able to initialize a static mutex object at link time. This means MutexBase has to be a POD and its member variables have to be public.

86713. The specialization for size 8.

86714. Formats an int value as "%X".

86715. Combine() allows the user to combine two or more sequences to produce values of a Cartesian product of those sequences' elements. Synopsis: Combine(gen1, gen2, ..., genN) - returns a generator producing sequences with elements coming from the Cartesian product of elements from the sequences generated by gen1, gen2, ..., genN. The sequence elements will have a type of tuple<T1, T2, ..., TN> where T1, T2, ..., TN are the types of elements from sequences produced by gen1, gen2, ..., genN. Combine can have up to 10 arguments. This number is currently limited by the maximum number of elements in the tuple implementation used by Google Test. Example: This will instantiate tests in test case AnimalTest each one with the parameter values tuple("cat", BLACK), tuple("cat", WHITE), tuple("dog", BLACK), and tuple("dog", WHITE): enum Color { BLACK, GRAY, WHITE }; class AnimalTest : public testing::TestWithParam<tuple<const char*, Color>> { ... }; TEST_P(AnimalTest, AnimalLooksNice) { ... } INSTANTIATE_TEST_CASE_P(AnimalVariations, AnimalTest, Combine(Values("cat", "dog"), Values(BLACK, WHITE))); This will instantiate tests in FlagDependentTest with all variations of two Boolean flags: class FlagDependentTest : public testing::TestWithParam<tuple<bool, bool>> { virtual void SetUp() { // Assigns external_flag_1 and external_flag_2 values from the tuple. tie(external_flag_1, external_flag_2) = GetParam(); } }; TEST_P(FlagDependentTest, TestFeature1) { // Test your code using external_flag_1 and external_flag_2 here. } INSTANTIATE_TEST_CASE_P(TwoBoolSequence, FlagDependentTest, Combine(Bool(), Bool()));

86716. **comment:** Defines a test. The first parameter is the name of the test case, and the second parameter is the name of the test within the test case. The convention is to end the test case name with "Test". For example, a test case for the Foo class can be named FooTest. Test code should appear between braces after an invocation of this macro. Example: TEST(FooTest, InitializesCorrectly) { Foo foo; EXPECT_TRUE(foo.StatusIsOK()); }

label: code-design

86717. Then, use TYPED_TEST_P() to define as many type-parameterized tests for this type-parameterized test case as you want.

86718. Determines whether to support Combine(). This only makes sense when value-parameterized tests are enabled. The implementation doesn't work on Sun Studio since it doesn't understand templated conversion operators.

86719. Class iterating over elements provided by an implementation of ParamGeneratorInterface<T>. It wraps ParamIteratorInterface<T> and implements the const forward iterator concept.

86720. For now, the XML report includes all tests matching the filter. In the future, we may trim tests that are excluded because of sharding.

86721. This constructor intentionally does nothing. It relies on type_ being statically initialized to 0 (effectively setting it to kStatic) and on ThreadSafeLazyInit() to lazily initialize the rest of the members.

86722. Types of SetUpTestCase() and TearDownTestCase() functions.

86723. The data type used to store the actual floating-point number.

86724. Macros for indicating success/failure in test code.

86725. Generator interface definition

86726. Wraps ParamGeneratorInterface<T> and provides general generator syntax compatible with the STL Container concept. This class implements copy initialization semantics and the contained ParamGeneratorInterface<T> instance is shared among all copies of the original object. This is possible because that instance is immutable.

86727. **comment:** Advance should not be called on beyond-of-range iterators so no component iterators must be beyond end of range, either.

label: code-design

86728. We define two overloaded versions of Compare(). The first version will be picked when the second argument to ASSERT_EQ() is NOT a pointer, e.g. ASSERT_EQ(0, AnIntFunction()) or EXPECT_EQ(false, a_bool).

86729. Implements the helper function for {ASSERT|EXPECT}_GE

86730. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhangyong Wan) The Google C++ Testing Framework (Google Test) This header file defines the Message class. IMPORTANT NOTE: Due to limitation of the C++ language, we have to leave some internal implementation details in this header file. They are clearly marked by comments like this: // INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM. Such code is NOT meant to be used by a user directly, and is subject to CHANGE WITHOUT NOTICE. Therefore DO NOT DEPEND ON IT in a user program!

86731. **comment:** The tests from the instantiation above will have these names: * AnotherInstantiationName/FooTest.DoesBlah/0 for "cat" *

AnotherInstantiationName/FooTest.DoesBlah/1 for "dog" * AnotherInstantiationName/FooTest.HasBlahBlah/0 for "cat" *

AnotherInstantiationName/FooTest.HasBlahBlah/1 for "dog" Please note that INSTANTIATE_TEST_CASE_P will instantiate all tests in the given test case,

whether their definitions come before or AFTER the INSTANTIATE_TEST_CASE_P statement. Please also note that generator expressions (including parameters to the generators) are evaluated in InitGoogleTest(), after main() has started. This allows the user on one hand, to adjust generator parameters in order to dynamically determine a set of tests to run and on the other hand, give the user a chance to inspect the generated tests with Google Test reflection API before RUN_ALL_TESTS() is executed. You can see samples/sample7_unittest.cc and samples/sample8_unittest.cc for more examples. In the future, we plan to publish the API for defining new parameter generators. But for now this interface remains part of the internal implementation and is subject to change. A parameterized test fixture must be derived from testing::Test and from testing::WithParamInterface<T>, where T is the type of the parameter values. Inheriting from TestWithParam<T> satisfies that requirement because TestWithParam<T> inherits from both Test and WithParamInterface. In more complicated hierarchies, however, it is occasionally useful to inherit separately from Test and WithParamInterface. For example:

label: code-design

86732. ADD_FAILURE unconditionally adds a failure to the current test. SUCCEED generates a success - it doesn't automatically make the current test successful, as a test is only successful when it has no failure. EXPECT_* verifies that a certain condition is satisfied. If not, it behaves like ADD_FAILURE. In particular: EXPECT_TRUE verifies that a Boolean condition is true, EXPECT_FALSE verifies that a Boolean condition is false. FAIL and ASSERT_* are similar to ADD_FAILURE and EXPECT_*, except that they will also abort the current function on failure. People usually want the fail-fast behavior of FAIL and ASSERT_*, but those writing data-driven tests often find themselves using ADD_FAILURE and EXPECT_* more.

86733. As a C-function, ThreadFuncWithCLinkage cannot be templated itself. Consequently, it cannot select a correct instantiation of ThreadWithParam in order to call its Run(). Introducing ThreadWithParamBase as a non-templated base class for ThreadWithParam allows us to bypass this problem.

86734. namespace internal namespace testing

86735. 40302 means version 4.3.2.

86736. test_names

86737. Expands to the name of the class that implements the given test.

86738. We disallow copying TestCases.

86739. **comment:** A class for indicating whether an assertion was successful. When the assertion wasn't successful, the AssertionResult object remembers a non-empty message that describes how it failed. To create an instance of this class, use one of the factory functions (AssertionSuccess() and AssertionFailure()). This class is useful for two purposes: 1. Defining predicate functions to be used with Boolean test assertions EXPECT_TRUE/EXPECT_FALSE and their ASSERT_ counterparts 2. Defining predicate-format functions to be used with predicate assertions (ASSERT_PRED_FORMAT*, etc). For example, if you define IsEven predicate: testing::AssertionResult IsEven(int n) { if ((n % 2) == 0) return testing::AssertionSuccess(); else return testing::AssertionFailure() << n << " is odd"; } Then the failed expectation EXPECT_TRUE(IsEven(Fib(5))) will print the message Value of: IsEven(Fib(5)) Actual: false (5 is odd) Expected: true instead of a more opaque Value of: IsEven(Fib(5)) Actual: false Expected: true in case IsEven is a simple Boolean predicate. If you expect your predicate to be reused and want to support informative messages in EXPECT_FALSE and ASSERT_FALSE (negative assertions show up about half as often as positive ones in our tests), supply messages for both success and failure cases: testing::AssertionResult IsEven(int n) { if ((n % 2) == 0) return testing::AssertionSuccess() << n << " is even"; else return testing::AssertionFailure() << n << " is odd"; } Then a statement EXPECT_FALSE(IsEven(Fib(6))) will print Value of: IsEven(Fib(6)) Actual: true (8 is even) Expected: false NB: Predicates that support negative Boolean assertions have reduced performance in positive ones so be careful not to use them in tests that have lots (tens of thousands) of positive Boolean assertions. To use this class with EXPECT_PRED_FORMAT assertions such as: // Verifies that Foo() returns an even number. EXPECT_PRED_FORMAT1(IsEven, Foo()); you need to define: testing::AssertionResult IsEven(const char* expr, int n) { if ((n % 2) == 0) return testing::AssertionSuccess(); else return testing::AssertionFailure() << "Expected: " << expr << " is even\n Actual: it's " << n; } If Foo() returns 5, you will see the following message: Expected: Foo() is even Actual: it's 5

label: code-design

86740. Makes a failed assertion result with the given failure message. Deprecated; use AssertionFailure() << msg.

86741. Returns the i-th test among all the tests. i can range from 0 to total_test_count() - 1. If i is not in that range, returns NULL.

86742. First, define a fixture class template. It should be parameterized by a type. Remember to derive it from testing::Test.

86743. Returns the i-th test part result among all the results. i can range from 0 to test_property_count() - 1. If i is not in that range, aborts the program.

86744. gcc and clang define __GXX_EXPERIMENTAL_CXX0X__ when -std={c,gnu}++{0x,11} is passed. The C++11 standard specifies a value for __cplusplus, and recent versions of clang, gcc, and probably other compilers set that too in C++11 mode.

86745. Returns true if FilePath ends with a path separator, which indicates that it is intended to represent a directory. Returns false otherwise. This does NOT check that a directory (or file) actually exists.

86746. An Environment object is capable of setting up and tearing down an environment. You should subclass this to define your own environment(s). An Environment object does the set-up and tear-down in virtual methods SetUp() and TearDown() instead of the constructor and the destructor, as: 1. You cannot safely throw from a destructor. This is a problem as in some cases Google Test is used where exceptions are enabled, and we may want to implement ASSERT_* using exceptions where they are available. 2. You cannot use ASSERT_* directly in a constructor or destructor.

86747. # of bits in a number.

86748. **comment:** The pure interface class that all value-parameterized tests inherit from. A value-parameterized class must inherit from both ::testing::Test and ::testing::WithParamInterface. In most cases that just means inheriting from ::testing::TestWithParam, but more complicated test hierarchies may need to inherit from Test and WithParamInterface at different levels. This interface has support for accessing the test parameter value via the GetParam() method. Use it with one of the parameter generator defining functions, like Range(), Values(), ValuesIn(), Bool(), and Combine(). class FooTest : public ::testing::TestWithParam<int> { protected: FooTest() { // Can use GetParam() here. } virtual ~FooTest() { // Can use GetParam() here. } virtual void SetUp() { // Can use GetParam() here. } virtual void TearDown() { // Can use GetParam() here. } }; TEST_P(FooTest, DoesBar) { // Can use GetParam() method here. Foo foo; ASSERT_TRUE(foo.DoesBar(GetParam())); } INSTANTIATE_TEST_CASE_P(OneToTenRange, FooTest, ::testing::Range(1, 10));

label: code-design

86749. Base case.

86750. The empty template list.

86751. sam represents a negative number.

86752. **comment:** We are on Windows CE, which has no environment variables. To prevent 'unused argument' warning.

label: code-design

86753. Fired after environment set-up for each iteration of tests ends.

86754. prefix

86755. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_DEATH_TEST_INTERNAL_H_

86756. Returns true if pathname describes a directory in the file-system that exists.

86757. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Generates values from the Cartesian product of values produced by the argument generators.

86758. A class representing the parsed contents of the --gtest_internal_run_death_test flag, as it existed when RUN_ALL_TESTS was called.

86759. class CartesianProductGenerator10

86760. Two predicate classes that can be used in {ASSERT,EXPECT}_EXIT*:

86761. Releases this mutex.

86762. When this flag is specified, tests' order is randomized on every iteration.

86763. The user didn't tell us whether ::wstring is available, so we need to figure it out.

86764. Generates a fatal failure with a generic message.

86765. The template "selector" struct TemplateSel<Tmpl> is used to represent Tmpl, which must be a class template with one type parameter, as a type.

TemplateSel<Tmpl>::Bind<T>::type is defined as the type Tmpl<T>. This allows us to actually instantiate the template "selected" by TemplateSel<Tmpl>. This trick is necessary for simulating typeid for class templates, which C++ doesn't support directly.

86766. **comment:** Internal utilities ----- The following macros and utilities are for Google Test's INTERNAL use only. Code outside Google Test MUST NOT USE THEM DIRECTLY. Macros for basic C++ coding: GTEST_AMBIGUOUS_ELSE_BLOCKER_- for disabling a gcc warning.

GTEST_ATTRIBUTE_UNUSED_- declares that a class' instances or a variable don't have to be used. GTEST_DISALLOW_ASSIGN_- disables operator=.

GTEST_DISALLOW_COPY_AND_ASSIGN_- disables copy ctor and operator=. GTEST_MUST_USE_RESULT_- declares that a function's result must be used. GTEST_INTENTIONAL_CONST_COND_PUSH_- start code section where MSVC C4127 is suppressed (constant conditional).

GTEST_INTENTIONAL_CONST_COND_POP_- finish code section where MSVC C4127 is suppressed. C++11 feature wrappers: testing::internal::move - portability wrapper for std::move. Synchronization: Mutex, MutexLock, ThreadLocal, GetThreadCount() - synchronization primitives. Template meta

programming: is_pointer - as in TR1; needed on Symbian and IBM XL C/C++ only. IteratorTraits - partial implementation of std::iterator_traits, which is not available in libCstd when compiled with Sun C++. Smart pointers: scoped_ptr - as in TR2. Regular expressions: RE - a simple regular expression class using the POSIX Extended Regular Expression syntax on UNIX-like platforms, or a reduced regular exception syntax on other platforms, including Windows. Logging:

GTEST_LOG_() - logs messages at the specified severity level. LogToStderr() - directs all log messages to stderr. FlushInfoLog() - flushes informational log messages. Stdout and stderr capturing: CaptureStdout() - starts capturing stdout. GetCapturedStdout() - stops capturing stdout and returns the captured string. CaptureStderr() - starts capturing stderr. GetCapturedStderr() - stops capturing stderr and returns the captured string. Integer types: TypeWithSize - maps an integer to a int type. Int32, UInt32, Int64, UInt64, TimeInMillis - integers of known sizes. BiggestInt - the biggest signed integer type. Command-line utilities: GTEST_DECLARE_*() - declares a flag. GTEST_DEFINE_*() - defines a flag. GetInjectableArgs() - returns the command line as a vector of strings. Environment variable utilities: GetEnv() - gets the value of an environment variable. BoolFromGTestEnv() - parses a bool environment variable. Int32FromGTestEnv() - parses an Int32 environment variable. StringFromGTestEnv() - parses a string environment variable.

label: code-design

86767. Defines this to true iff Google Test can use POSIX regular expressions.

86768. Returns the name of the parameter type, or NULL if this is not a typed or a type-parameterized test.

86769. Type and function utilities for implementing parameterized tests. This file is generated by a SCRIPT. DO NOT EDIT BY HAND! Currently Google Test supports at most 50 arguments in Values, and at most 10 arguments in Combine. Please contact googletestframework@googlegroups.com if you need more. Please note that the number of arguments to Combine is limited by the maximum arity of the implementation of tuple which is currently set at 10.

86770. Determines whether the system compiler uses UTF-16 for encoding wide strings.

86771. When this flag is set with a "host:port" string, on supported platforms test results are streamed to the specified port on the specified host machine.

86772. **comment:** Type-parameterized tests are abstract test patterns parameterized by a type. Compared with typed tests, type-parameterized tests allow you to define the test pattern without knowing what the type parameters are. The defined pattern can be instantiated with different types any number of times, in any number of translation units. If you are designing an interface or concept, you can define a suite of type-parameterized tests to verify properties that any valid implementation of the interface/concept should have. Then, each implementation can easily instantiate the test suite to verify that it conforms to the requirements, without having to write similar tests repeatedly. Here's an example:

label: test

86773. is_pointer

86774. **comment:** We put our data in a struct so that the size of the AssertHelper class can be as small as possible. This is important because gcc is incapable of re-using stack space even for temporary variables, so every EXPECT_EQ reserves stack space for another AssertHelper.

label: code-design

86775. **comment:** Separate the error generating code from the code path to reduce the stack frame size of CmpHelperEQ. This helps reduce the overhead of some sanitizers when calling EXPECT_* in a tight loop.

label: code-design

86776. GTEST_OS_LINUX

86777. IWYU pragma: export

86778. Forward declarations of ValuesIn(), which is implemented in include/gtest/gtest-param-test.h.

86779. 6.1.3.5 Relational operators

86780. Constructs a TestInfo object. The newly constructed instance assumes ownership of the factory object.

86781. !GTEST_OS_WINDOWS_MOBILE && !GTEST_OS_SYMBIAN GTEST_HAS_STREAM_REDIRECTION

86782. Asserts that val1 is less than, or almost equal to, val2. Fails otherwise. In particular, it fails if either val1 or val2 is NaN.

86783. Converts a streamable value to an std::string. A NULL pointer is converted to "(null)". When the input value is a ::string, ::std::string, ::wstring, or ::std::wstring object, each NUL character in it is replaced with "\\0".

86784. A handy wrapper around RemoveReference that works when the argument T depends on template parameters.

86785. This default version is called when kTypeKind is kOtherType.

86786. A cached value of *iterator_. We keep it here to allow access by pointer in the wrapping iterator's operator->(). value_ needs to be mutable to be accessed in Current(). Use of scoped_ptr helps manage cached value's lifetime, which is bound by the lifespan of the iterator itself.

86787. **comment:** Compile-time assertion for type equality. StaticAssertTypeEq<type1, type2>() compiles iff type1 and type2 are the same type. The value it returns is not interesting. Instead of making StaticAssertTypeEq a class template, we make it a function template that invokes a helper class template. This prevents a user from misusing StaticAssertTypeEq<T1, T2> by defining objects of that type. CAVEAT: When used inside a method of a class template, StaticAssertTypeEq<T1, T2>() is effective ONLY IF the method is instantiated. For example, given: template <typename T> class Foo { public: void Bar() { testing::StaticAssertTypeEq<int, T>(); } }; the code: void Test1() { Foo<bool> foo; } will NOT generate a compiler error, as Foo<bool>::Bar() is never actually instantiated. Instead, you need: void Test2() { Foo<bool> foo; foo.Bar(); } to cause a compiler error.

label: code-design

86788. Returns true if the given test should run.

86789. Waits for the death test to finish and returns its status.

86790. By default, print C string as pointers to be safe, as we don't know whether they actually point to a NUL-terminated string.

86791. If input name has a trailing separator character, removes it and returns the name, otherwise return the name string unmodified. On Windows platform, uses \ as the separator, other platforms use /.

86792. GTEST_HAS_GLOBAL_WSTRING

86793. This version will be picked when the second argument to ASSERT_EQ() is a pointer, e.g. ASSERT_EQ(NULL, a_pointer).

86794. The GNU compiler emits a warning if nested "if" statements are followed by an "else" statement and braces are not used to explicitly disambiguate the "else" binding. This leads to problems with code like: if (gate) ASSERT_*(condition) << "Some message"; The "switch (0) case 0:" idiom is used to suppress this.

86795. Now the tricky part: you need to register all test patterns before you can instantiate them. The first argument of the macro is the test case name; the rest are the names of the tests in this test case.

86796. A helper for suppressing warnings on constant condition. It just returns 'condition'.

86797. Use this function in main() to run all tests. It returns 0 if all tests are successful, or 1 otherwise. RUN_ALL_TESTS() should be invoked after the command line has been parsed by InitGoogleTest(). This function was formerly a macro; thus, it is in the global namespace and has an all-caps name.

86798. __has_feature(thread_sanitizer)

86799. Predicate-formatters for implementing the HRESULT checking macros {ASSERT|EXPECT}_HRESULT_{SUCCEEDED|FAILED} We pass a long instead of HRESULT to avoid causing an include dependency for the HRESULT type.

86800. For other compilers, we assume exceptions are disabled to be conservative.

86801. Overloads for ::wstring and ::std::wstring.

86802. Returns true iff the test passed (i.e. no test part failed).

86803. Used in the EXPECT_TRUE/FALSE(bool_expression). T must be contextually convertible to bool. The second parameter prevents this overload from being considered if the argument is implicitly convertible to AssertionResult. In that case we want AssertionResult's copy constructor to be used.

86804. Helper function for implementing {EXPECT|ASSERT}_PRED3. Don't use this in your code.

86805. 6.1.4 Pairs. Unimplemented.

86806. class RangeGenerator::Iterator

86807. Sets a new value, overriding the one supplied in the constructor.

86808. NDEBUG for EXPECT_DEBUG_DEATH GTEST_HAS_DEATH_TEST

86809. GTEST_INCLUDE_GTEST_GTEST_PROD_H Copyright 2008, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: mheule@google.com (Markus Heule)

86810. WINAPI_FAMILY defined but no known partition matched. Default to desktop.

86811. The helper function for {ASSERT|EXPECT}_EQ.
86812. Returns repeater that broadcasts the TestEventListener events to all subscribers.
86813. ParamGeneratorInterface<T> is the binary interface to access generators defined in other translation units.
86814. The following macros are useful for writing death tests.
86815. Overloads for C strings.
86816. Assume no SEH.
86817. **comment:** The result of a single Test. This includes a list of TestPartResults, a list of TestProperties, a count of how many death tests there are in the Test, and how much time it took to run the Test. TestResult is not copyable.
label: test
86818. Inspired by boost/config/stdcpp3.hpp, http://gcc.gnu.org/gcc-4.2/changes.html and
<http://gcc.gnu.org/onlinedocs/libstdc++/manual/bk01pt01ch01.html#manual.intro.status.standard.200x>
86819. Represents time in milliseconds.
86820. Assumes one of the above roles.
86821. A copy of all command line arguments. Set by InitGoogleTest().
86822. Finally, you are free to instantiate the pattern with the types you want. If you put the above code in a header file, you can #include it in multiple C++ source files and instantiate it multiple times. To distinguish different instances of the pattern, the first argument to the INSTANTIATE_* macro is a prefix that will be added to the actual test case name. Remember to pick unique prefixes for different instances.
86823. Compares two wide C strings. Returns true iff they have the same content. Unlike wcscmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.
86824. With this overloaded version, we allow anonymous enums to be used in {ASSERT|EXPECT}_EQ when compiled with gcc 4, as anonymous enums can be implicitly cast to BiggestInt. Even though its body looks the same as the above version, we cannot merge the two, as it will make anonymous enums unhappy.
86825. Internal macro for implementing {EXPECT|ASSERT}_PRED4. Don't use this in your code.
86826. Determines whether to support type-driven tests.
86827. **comment:** The user didn't tell us whether ::std::wstring is available, so we need to figure it out. TODO(wan@google.com): uses autoconf to detect whether ::std::wstring is available.
label: requirement
86828. Returns the test name.
86829. A simple C++ wrapper for <regex.h>. It uses the POSIX Extended Regular Expression syntax.
86830. This flag temporary enables the disabled tests.
86831. **comment:** Gets the number of disabled tests that will be reported in the XML report.
label: test
86832. class RangeGenerator
86833. Copyright 2008 Google Inc. All Rights Reserved. Author: wan@google.com (Zhanyong Wan)
86834. Typed (aka type-driven) tests repeat the same test for types in a list. You must know which types you want to test with when writing typed tests. Here's how you do it:
86835. namespace tr1 namespace std
86836. Returns true iff this test will appear in the XML report.
86837. This flag enables using colors in terminal output. Available values are "yes" to enable colors, "no" (disable colors), or "auto" (the default) to let Google Test decide.
86838. Returns the random seed used at the start of the current test run.
86839. The following line prevents this overload from being considered if T2 is not a pointer type. We need this because ASSERT_EQ(NULL, my_ptr) expands to Compare("", "", NULL, my_ptr), which requires a conversion to match the Secret* in the other overload, which would otherwise make this template match better.
86840. Not meant to be instantiated. class String
86841. This flag controls the style of death tests. Valid values are "threadsafe", meaning that the death test child process will re-execute the test binary from the start, running only a single death test, or "fast", meaning that the child process will execute the test logic immediately after forking.
86842. The default case.
86843. Defines scoped_ptr.
86844. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. ParameterizedTestCaseRegistry contains a map of ParameterizedTestCaseInfoBase classes accessed by test case names. TEST_P and INSTANTIATE_TEST_CASE_P macros use it to locate their corresponding ParameterizedTestCaseInfo descriptors.
86845. **comment:** A macro to disallow copy constructor and operator= This should be used in the private: declarations for a class.
label: code-design
86846. The elapsed time, in milliseconds.
86847. Includes the auto-generated header that implements a family of generic predicate assertion macros. Copyright 2006, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE.
86848. Protects mutable state of the property vector and of owned properties, whose values may be updated.
86849. class FilePath
86850. Next, associate a list of types with the test case, which will be repeated for each type in the list. The typedef is necessary for the macro to parse correctly.
86851. D'tor. Do not inherit from TestResult.
86852. INTERNAL IMPLEMENTATION - DO NOT USE. GTEST_CHECK_ is an all-mode assert. It aborts the program if the condition is not satisfied. Synopsis: GTEST_CHECK_(boolean_condition); or GTEST_CHECK_(boolean_condition) << "Additional message"; This checks the condition and if the condition is not satisfied it prints message about the condition violation, including the condition itself, plus additional message streamed into it, if any, and then it aborts the program. It aborts the program irrespective of whether it is built in the debug mode or not.
86853. **comment:** Often a user misspells SetUp() as Setup() and spends a long time wondering why it is never called by Google Test. The declaration of the following method is solely for catching such an error at compile time: - The return type is deliberately chosen to be not void, so it will be a conflict if void Setup() is declared in the user's test fixture. - This method is private, so it will be another compiler error if the method is called from the user's test fixture. DO NOT OVERRIDE THIS FUNCTION. If you see an error about overriding the following function or about it being private, you have mis-spelled SetUp() as Setup().
label: code-design
86854. **comment:** NOLINT NOLINT GTEST_OS_WINDOWS

label: test

86855. Gets the number of tests that should run.
86856. Returns true if pathname describes an absolute path.
86857. Visual Studio 2010, 2012, and 2013 define symbols in std::tr1 that conflict with our own definitions. Therefore using our own tuple does not work on those compilers.

86858. **comment:** Suppresses MSVC warnings 4072 (unreachable code) for the code following statement if it returns or throws (or doesn't return or throw in some situations).

label: code-design

86859. Returns true if exit_status describes a process that was terminated by a signal, or exited normally with a nonzero exit code.

86860. Protects copying of all linked_ptr objects.

86861. Gets the number of all tests in this test case.

86862. GCC 4.4.7

86863. Turns const U&, U&, const U, and U all into U.

86864. Gets the number of successful test cases.

86865. GTEST_OS_WINDOWS

86866. Determines whether Google Test can use the pthreads library.

86867. Allows streaming basic output manipulators such as endl or flush into this object.

86868. **comment:** Google Test - The Google C++ Testing Framework This file implements a universal value printer that can print a value of any type T: void ::testing::internal::UniversalPrinter<T>::Print(value, ostream_ptr); A user can teach this function how to print a class type T by defining either operator<<() or PrintTo() in the namespace that defines T. More specifically, the FIRST defined function in the following list will be used (assuming T is defined in namespace foo): 1. foo::PrintTo(const T&, ostream*) 2. operator<<(ostream&, const T&) defined in either foo or the global namespace. If none of the above is defined, it will print the debug string of the value if it is a protocol buffer, or print the raw bytes in the value otherwise. To aid debugging: when T is a reference type, the address of the value is also printed; when T is a (const) char pointer, both the pointer value and the NUL-terminated string it points to are printed. We also provide some convenient wrappers: // Prints a value to a string. For a (const or not) char // pointer, the NUL-terminated string (but not the pointer) is // printed. std::string ::testing::PrintToString(const T& value); // Prints a value tersely: for a reference type, the referenced // value (but not the address) is printed; for a (const or not) char // pointer, the NUL-terminated string (but not the pointer) is // printed. void ::testing::internal::UniversalTersePrint(const T& value, ostream*); // Prints value using the type inferred by the compiler. The difference // from UniversalTersePrint() is that this function prints both the // pointer and the NUL-terminated string for a (const or not) char pointer. void ::testing::internal::UniversalPrint(const T& value, ostream*); // Prints the fields of a tuple tersely to a string vector, one // element for each field. Tuple support must be enabled in // gtest-port.h. std::vector<string> UniversalTersePrintTupleFieldsToStrings(const Tuple& value); Known limitation: The print primitives print the elements of an STL-style container using the compiler-inferred type of *iter where iter is a const_iterator of the container. When const_iterator is an input iterator but not a forward iterator, this inferred type may not match value_type, and the print output may be incorrect. In practice, this is rarely a problem as for most containers const_iterator is a forward iterator. We'll fix this if there's an actual need for it. Note that this fix cannot rely on value_type being defined as many user-defined container types don't have value_type.

label: code-design

86869. The c'tor pushes the given source file location and message onto a trace stack maintained by Google Test.

86870. Brings in definitions for functions used in the testing::internal::posix namespace (read, write, close, chdir, isatty, stat). We do not currently use them on Windows Mobile.

86871. Determines whether to support stream redirection. This is used to test output correctness and to implement death tests.

86872. Creates a Test object.

86873. class CartesianProductGenerator4::Iterator

86874. **comment:** The abstract class that all tests inherit from. In Google Test, a unit test program contains one or many TestCases, and each TestCase contains one or many Tests. When you define a test using the TEST macro, you don't need to explicitly derive from Test - the TEST macro automatically does this for you. The only time you derive from Test is when defining a test fixture to be used a TEST_F. For example: class FooTest : public testing::Test { protected: void SetUp() override { ... } void TearDown() override { ... } ... }; TEST_F(FooTest, Bar) { ... } TEST_F(FooTest, Baz) { ... } Test is not copyable.

label: code-design

86875. This flag sets up the filter to select by name using a glob pattern the tests to run. If the filter is not given all tests are executed.

86876. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_PORT_H_

86877. GTEST_HAS_STREAM_REDIRECTION

86878. Base class for ValueHolder<T>. Allows a caller to hold and delete a value without knowing its type.

86879. **comment:** Returns the TestCase object for the test that's currently running, or NULL if no test is running.

label: test

86880. defined(_MSC_VER) || defined(__BORLANDC__) GTEST_HAS_EXCEPTIONS

86881. 6.1.3.2 Tuple creation functions.

86882. Anything in namespace gtest_internal is Google Test's INTERNAL IMPLEMENTATION DETAIL and MUST NOT BE USED DIRECTLY in user code.

86883. This overload prints a (const) char array compactly.

86884. **comment:** FilePath - a class for file and directory pathname manipulation which handles platform-specific conventions (like the pathname separator). Used for helper functions for naming files in a directory for xml output. Except for Set methods, all methods are const or static, which provides an "immutable value object" -- useful for peace of mind. A FilePath with a value ending in a path separator ("like>this/") represents a directory, otherwise it is assumed to represent a file. In either case, it may or may not represent an actual file or directory in the file system. Names are NOT checked for syntax correctness -- no checking for illegal characters, malformed paths, etc.

label: code-design

86885. GTEST_INCLUDE_GTEST_GTEST_TYPED_TEST_H_

86886. For FullMatch(). For PartialMatch().

86887. STLport, provided with the Android NDK, has neither <tr1/tuple> or <tuple>.

86888. This is the only specialization that allows VC++ 7.1 to remove const in 'const int[3]' and 'const int[3][4]'. However, it causes trouble with GCC and thus needs to be conditionally compiled.

86889. IWYU pragma: export // NOLINT

86890. namespace internal

86891. Helper function for *_STRNE on wide strings. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86892. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. TestMetaFactory creates test factories for passing into MakeAndRegisterTestInfo function. Since MakeAndRegisterTestInfo receives ownership of test factory pointer, same factory object cannot be passed into that method twice. But ParameterizedTestCaseInfo is going to call it for each Test/Parameter value combination. Thus it needs meta factory creator class.

86893. Passing non-POD classes through ellipsis (...) crashes the ARM compiler and generates a warning in Sun Studio. The Nokia Symbian and the IBM XL C/C++ compiler try to instantiate a copy constructor for objects passed through ellipsis (...), failing for uncopyable objects. We define this to ensure that only POD is passed through ellipsis on these systems.

86894. Fired after all test activities have ended.

86895. Returns the standard listener responsible for the default XML output controlled by the --gtest_output=xml flag. Can be removed from the listeners list by users who want to shut down the default XML output controlled by this flag and substitute it with custom one. Note that removing this object from the listener list with Release transfers its ownership to the caller and makes this function return NULL the next time.

86896. GCC 4.5.3

86897. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. ParameterizedTestCaseInfo accumulates tests obtained from TEST_P macro invocations for a particular test case and generators obtained from INSTANTIATE_TEST_CASE_P macro invocations for that test case. It registers tests with all values generated by all generators when asked.

86898. Array.

86899. Gets the user supplied key.

86900. The type of basic IO manipulators (endl, ends, and flush) for narrow streams.

86901. We need to use cached value referenced by iterator_ because *iterator_ can return a temporary object (and of type other than T), so just having "return &*iterator_;" doesn't work. value_ is updated here and not in Advance() because Advance() can advance iterator_ beyond the end of the range, and we cannot

detect that fact. The client code, on the other hand, is responsible for not calling Current() on an out-of-range iterator.

86902. The user didn't tell us whether exceptions are enabled, so we need to figure it out.

86903. Next, recurses (at compile time) with the tail of the type list.

86904. This prevents the user from using TypeWithSize<N> with incorrect values of N.

86905. GTEST_OS_LINUX && !defined(__ia64__)

86906. file

86907. Thread annotations

86908. Returns true iff the path is "".

86909. Returns the TestResult that holds test properties recorded during execution of SetUpTestCase and TearDownTestCase.

86910. Returns the current working directory, or "" if unsuccessful.

86911. To visit static members of the fixture, add theTestFixture:: prefix.

86912. Ctor. TestProperty does NOT have a default constructor. Always use this constructor (with parameters) to create a TestProperty object.

86913. Fired before the test starts.

86914. Create returns false if there was an error determining the appropriate action to take for the current death test; for example, if the gtest_death_test_style flag is set to an invalid value. The LastMessage method will return a more detailed message in that case. Otherwise, the DeathTest pointer pointed to by the "test" argument is set. If the death test should be skipped, the pointer is set to NULL; otherwise, it is set to the address of a new concrete DeathTest object that controls the execution of the current test.

86915. **comment:** An enumeration of the three reasons that a test might be aborted.
label: test

86916. Prints the given number of bytes in the given object to the given ostream.

86917. Converts a wide C string to a String using the UTF-8 encoding. NULL will be converted to "(null)". If an error occurred during the conversion, "(failed to convert from wide string)" is returned.

86918. Windows CE does not define _snprintf_s and MSVC prior to 2005 doesn't complain about _snprintf.

86919. Macros for disabling Microsoft Visual C++ warnings. GTEST_DISABLE_MSC_WARNINGS_PUSH_(4800 4385) /* code that triggers warnings C4800 and C4385 */ GTEST_DISABLE_MSC_WARNINGS_POP_()

86920. NOLINT

86921. Returns a pointer to the last occurrence of a valid path separator in the FilePath. On Windows, for example, both '/' and '\' are valid path separators. Returns NULL if no path separator was found.

86922. TuplePolicy<TupleT> must provide: - tuple_size size of tuple TupleT. - get<size_t I>(const TupleT& t) static function extracting element I of tuple TupleT. - tuple_element<size_t I>::type type of element I of tuple TupleT.

86923. The usual test fixture members go here too.

86924. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Stores a parameter value and later creates tests parameterized with that value.

86925. The d'tor is virtual as we intend to inherit from Test.

86926. Increments the death test count, returning the new count.

86927. A function level attribute to disable checking for use of uninitialized memory when built with MemorySanitizer.

86928. dummy_ must not have a const type. Otherwise an overly eager compiler (e.g. MSVC 7.1 & 8.0) may try to merge TypeIdHelper<T>::dummy_ for different Ts as an "optimization".

86929. The compiler is required to allocate a different TypeIdHelper<T>::dummy_ variable for each T used to instantiate the template. Therefore, the address of dummy_ is guaranteed to be unique.

86930. Accessors for the implementation object.

86931. Constructs from a native array. Copies the source.

86932. The base case for the compile time recursion.

86933. The name of the source file where the test part took place, or "" if the source file is unknown.

86934. Returns the number of threads running in the process, or 0 to indicate that we cannot detect it.

86935. __BORLANDC__

86936. A unique struct template used as the default value for the arguments of class template Templates. This allows us to simulate variadic templates (e.g. Templates<int>, Templates<int, double>, and etc), which C++ doesn't support directly.

86937. We include tr1::tuple even if std::tuple is available to define printers for them.

86938. Returns true iff this is NAN (not a number).

86939. This helper template allows PrintTo() for tuples and UniversalTersePrintTupleFieldsToStrings() to be defined by induction on the number of tuple fields. The idea is that TuplePrefixPrinter<N>::PrintPrefixTo(t, os) prints the first N fields in tuple t, and can be defined in terms of TuplePrefixPrinter<N - 1>. The inductive case.

86940. expected(NULL)

86941. **comment:** The possible outcomes of a test part (i.e. an assertion or an explicit SUCCEED(), FAIL(), or ADD_FAILURE()).
label: test

86942. Helper function for *_STREQ on wide strings. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86943. Helper for suppressing false warning from Clang on a const char* variable declared in a conditional expression always being NULL in the else branch.

86944. Implements printing an array type T[N].

86945. GTEST_HAS_PARAM_TEST

86946. Helper template function for comparing floating-points. Template parameter: RawType: the raw floating-point type (either float or double) INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86947. GCC >= 4.6.0

86948. **comment:** Due to C++ preprocessor weirdness, we need double indirection to concatenate two tokens when one of them is __LINE__. Writing foo ## __LINE__ will result in the token foo__LINE__, instead of foo followed by the current line number. For more details, see <http://www.parashift.com/c++-faq-lite/misc-technical-issues.html#faq-39.6>
label: code-design

86949. Streams a custom failure message into this object.

86950. scripts/fuse_gtest.py depends on gtest's own header being #included *unconditionally*. Therefore these #includes cannot be moved inside #if GTEST_HAS_PARAM_TEST.

86951. The maximum number a BiggestInt can represent. This definition works no matter BiggestInt is represented in one's complement or two's complement. We cannot rely on numeric_limits in STL, as __int64 and long long are not part of standard C++ and numeric_limits doesn't need to be defined for them.

86952. The symbol "fail" here expands to something into which a message can be streamed.

86953. The raw floating-point number. The bits that represent the number.

86954. Gets the elapsed time, in milliseconds.

86955. **comment:** We use a const char* instead of an std::string, as Google Test used to be used where std::string is not available. TODO(wan@google.com): change to std::string.
label: code-design

86956. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. TestMetaFactoryBase is a base class for meta-factories that create test factories for passing into MakeAndRegisterTestInfo function.

86957. In order to catch the mistake of putting tests that use different test fixture classes in the same test case, we need to assign unique IDs to fixture classes and compare them. The TypeId type is used to hold such IDs. The user should treat TypeId as an opaque type: the only operation allowed on TypeId values is to compare them for equality using the == operator.

86958. GTEST_TUPLE_NAMESPACE_

86959. __clang__

86960. Formats a byte as "%02X".

86961. Fired before environment set-up for each iteration of tests starts.

86962. If a C string is compared with an STL string object, we know it's meant to point to a NUL-terminated string, and thus can print it as a string.

86963. !__BORLANDC__

86964. # of fraction bits in a number.

86965. **comment:** MSVC warns about implicitly converting from double to int for possible loss of data, so we need to temporarily disable the warning.

label: code-design

86966. class ValuesInIteratorRangeGenerator::Iterator

86967. Binary predicate assertion macros.

86968. Leave whatever circle we're part of. Returns true if we were the last member of the circle. Once this is done, you can join() another.

86969. Define this macro to 1 to omit the definition of FAIL(), which is a generic name and clashes with some other libraries.

86970. Runs the test after the test fixture has been set up. A sub-class must implement this to define the test logic. DO NOT OVERRIDE THIS FUNCTION DIRECTLY IN A USER PROGRAM. Instead, use the TEST or TEST_F macro.

86971. namespace edit_distance

86972. C++11 puts its tuple into the ::std namespace rather than ::std::tr1. gtest expects tuple to live in ::std::tr1, so put it there. This causes undefined behavior, but supported compilers react in the way we intend.

86973. Succeeded. Failed but the test can continue. Failed and the test should be terminated.

86974. Destroys the managed object for the current thread, if any.

86975. **comment:** True iff any test in this test case should run.

label: test

86976. Platform-indicating macros ----- Macros indicating the platform on which Google Test is being used (a macro is defined to 1 if compiled on the given platform; otherwise UNDEFINED -- it's never defined to 0.). Google Test defines these macros automatically. Code outside Google Test MUST NOT define them. GTEST_OS_AIX - IBM AIX GTEST_OS_CYGWIN - Cygwin GTEST_OS_FREEBSD - FreeBSD GTEST_OS_HPUX - HP-UX GTEST_OS_LINUX - Linux GTEST_OS_LINUX_ANDROID - Google Android GTEST_OS_MAC - Mac OS X GTEST_OS_IOS - iOS GTEST_OS_NACL - Google Native Client (NaCl) GTEST_OS_OPENBSD - OpenBSD GTEST_OS_QNX - QNX GTEST_OS_SOLARIS - Sun Solaris GTEST_OS_SYMBIAN - Symbian GTEST_OS_WINDOWS - Windows (Desktop, MinGW, or Mobile) GTEST_OS_WINDOWS_DESKTOP - Windows Desktop GTEST_OS_WINDOWS_MINGW - MinGW GTEST_OS_WINDOWS_MOBILE - Windows Mobile GTEST_OS_WINDOWS_PHONE - Windows Phone GTEST_OS_WINDOWS_RT - Windows Store App/WinRT GTEST_OS_ZOS - z/OS Among the platforms, Cygwin, Linux, Max OS X, and Windows have the most stable support. Since core members of the Google Test project don't have access to other platforms, support for them may be less stable. If you notice any problems on your platform, please notify googletestframework@googlegroups.com (patches for fixing them are even more welcome!). It is possible that none of the GTEST_OS_* macros are defined.

86977. Asserts that a given statement causes the program to exit, with an integer exit status that satisfies predicate, and emitting error output that matches regex.

Author: wan@google.com (Zhanyong Wan) The Google C++ Testing Framework (Google Test) This header file defines the public API for Google Test. It should be included by any test program that uses Google Test. IMPORTANT NOTE: Due to limitation of the C++ language, we have to leave some internal implementation details in this header file. They are clearly marked by comments like this: // INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM. Such code is NOT meant to be used by a user directly, and is subject to CHANGE WITHOUT NOTICE. Therefore DO NOT DEPEND ON IT in a user program! Acknowledgment: Google Test borrowed the idea of automatic test registration from Barthelemy Dagenais' (barthelemy@prologue.com) easyUnit framework.

86979. GTEST_ASSERT_ is the basic statement to which all of the assertions in this file reduce. Don't use this in your code.

86980. On some platforms, <regex.h> needs someone to define size_t, and won't compile otherwise. We can #include it here as we already included <stdlib.h>, which is guaranteed to define size_t through <stddef.h>. NOLINT

86981. GTEST_HAS_COMBINE

86982. Runs every test in this TestCase.

86983. Note: we deliberately don't call this PrintTo(), as that name conflicts with ::testing::internal::PrintTo in the body of the function.

86984. The mask for the fraction bits.

86985. Gets the (mutable) vector of TestInfos in this TestCase.

86986. Inspired by boost/config/stdlib/dinkumware.hpp

86987. Streams a value (either a pointer or not) to this object.

86988. GTEST_HAS_TYPED_TEST || GTEST_HAS_TYPED_TEST_P

86989. A workarond for the bug in VC++ 7.1 that prevents us from instantiating UniversalPrinter with T directly.

86990. begin[i]_ and end[i]_ define the i-th range that Iterator traverses. current[i]_ is the actual traversing iterator.

86991. Having the same base generator guarantees that the other iterator is of the same type and we can downcast.

86992. Most value-parameterized classes can ignore the existence of WithParamInterface, and can just inherit from ::testing::TestWithParam.

86993. Creates an empty UnitTest.

86994. enabler

86995. ByRef<T>::type is T if T is a reference; otherwise it's const T&.

86996. The helper function for {ASSERT|EXPECT}_STRCASEEQ. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

86997. GetParam works just the same here as if you inherit from TestWithParam.

86998. Removes const from a type if it is a const type, otherwise leaves it unchanged. This is the same as tr1::remove_const, which is not widely available yet.

86999. OS detection

87000. We cannot use std::numeric_limits<T>::max() as it clashes with the max() macro defined by <windows.h>.

87001. This overload is used when k >= 1.

87002. GTEST_INCLUDE_GTEST_GTEST_PARAM_TEST_H_ Copyright 2006, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. Author: wan@google.com (Zhanyong Wan) Google C++ Testing Framework definitions useful in production code.

87003. **comment:** C++ doesn't allow casting from a function pointer to any object pointer. IsTrue() silences warnings: "Condition is always true", "unreachable code".

label: code-design

87004. Returns true iff the test fatally failed.

87005. Helper macro for defining tests.

87006. GTEST_HAS_TR1_TUPLE

87007. The biggest signed integer type the compiler supports.

87008. Generates a nonfatal failure with a generic message.

87009. At this point we are sure that the object we found is of the same type we are looking for, so we downcast it to that type without further checks.
87010. Pops a trace from the per-thread Google Test trace stack.
87011. class CartesianProductGenerator2
87012. gtest-port.h guarantees to #include <pthread.h> when GTEST_HAS_PTHREAD is true. NOLINT
87013. 6.1.3.4 Element access.
87014. GetTypeName<T>() returns a human-readable name of type T. NB: This function is also used in Google Mock, so don't move it inside of the typed-test-only section below.
87015. Returns true iff the current test has the same fixture class as the first test in the current test case.
87016. With this overloaded version, we allow anonymous enums to be used in {ASSERT|EXPECT}_EQ when compiled with gcc 4, as anonymous enums can be implicitly cast to BiggestInt.
87017. Invoked when a ThreadLocal instance is destroyed.
87018. Deletes self. We deliberately pick an unusual name for this internal method to avoid clashing with names used in user TESTs.
87019. In theory, defining stuff in the ::std namespace is undefined behavior. We can do this as we are playing the role of a standard library vendor.
87020. Initializes owner_thread_id_ and critical_section_ in static mutexes.
87021. Returns true iff the unit test passed (i.e. all test cases passed).
87022. Bool() allows generating tests with parameters in a set of (false, true). Synopsis: Bool() - returns a generator producing sequences with elements {false, true}. It is useful when testing code that depends on Boolean flags. Combinations of multiple flags can be tested when several Bool()'s are combined using Combine() function. In the following example all tests in the test case FlagDependentTest will be instantiated twice with parameters false and true. class FlagDependentTest : public testing::TestWithParam<bool> { virtual void SetUp() { external_flag = GetParam(); } } INSTANTIATE_TEST_CASE_P(BoolSequence, FlagDependentTest, Bool());
87023. The user didn't tell us explicitly, so we make reasonable assumptions about which platforms have pthreads support. To disable threading support in Google Test, add -DGTEST_HAS_PTHREAD=0 to your compiler flags.
87024. Forward-declares a static mutex.
87025. Initializes Google Test. This must be called before calling RUN_ALL_TESTS(). In particular, it parses a command line for the flags that Google Test recognizes. Whenever a Google Test flag is seen, it is removed from argv, and *argc is decremented. No value is returned. Instead, the Google Test flag variables are updated. Calling the function for the second time has no user-visible effect.
87026. <regex.h> is not available on Windows. Use our own simple regex implementation instead.
87027. Converts the given wide string to a narrow string using the UTF-8 encoding, and streams the result to this Message object.
87028. The user didn't tell us whether RTTI is enabled, so we need to figure it out.
87029. GetTypeId<T>() returns the ID of type T. Different values will be returned for different types. Calling the function twice with the same type argument is guaranteed to return the same ID.
87030. Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhanyong Wan) The Google C++ Testing Framework (Google Test) This header file defines the public API for death tests. It is #included by gtest.h so a user doesn't need to include this directly.
87031. Returns the number of the test properties.
87032. Returns the fraction bits of this number.
87033. C++Builder cannot use member overload resolution during template instantiation. The simplest workaround is to use its C++0x type traits functions (C++Builder 2009 and above only).
87034. When printing a plain char, we always treat it as unsigned. This way, the output won't be affected by whether the compiler thinks char is signed or not.
87035. Skips to the first non-space char after the first comma in 'str'; returns NULL if no comma is found in 'str'.
87036. **comment:** Helpers for suppressing warnings on unreachable code or constant condition.
 label: code-design
87037. GTEST_OS_SYMBIAN
87038. **comment:** A macro for implementing the helper functions needed to implement ASSERT_?? and EXPECT_?. It is here just to avoid copy-and-paste of similar code. For each templated helper function, we also define an overloaded version for BiggestInt in order to reduce code bloat and allow anonymous enums to be used with {ASSERT|EXPECT}_?? when compiled with gcc 4. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
 label: code-design
87039. We don't support MSVC 7.1 with exceptions disabled now. Therefore all the compilers we care about are adequate for supporting value-parameterized tests.
87040. Copy constructor. Used in EXPECT_TRUE/FALSE(assertion_result).
87041. namespace testing
87042. iteration
87043. Sets up the stuff shared by all tests in this test case. Google Test will call Foo::SetUpTestCase() before running the first test in test case Foo. Hence a sub-class can define its own SetUpTestCase() method to shadow the one defined in the super class.
87044. namespace internal2 namespace testing
87045. This flag specifies the maximum number of stack frames to be printed in a failure message.
87046. Pointer to the function that sets up the test case.
87047. Returns true if pathname describes a root directory. (Windows has one root directory per disk drive.)
87048. Overload for std::pair.
87049. Same as above, but the input is represented as strings.
87050. **comment:** unused
 label: code-design
87051. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_LINKED_PTR_H_ Copyright 2007, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Author: wan@google.com (Zhanyong Wan)
87052. Type lists of length 1, 2, 3, and so on.
87053. Next, declare that you will define a type-parameterized test case (the _P suffix is for "parameterized" or "pattern", whichever you prefer).
87054. AssertTypeEq<T1, T2>::type is defined iff T1 and T2 are the same type. This can be used as a compile-time assertion to ensure that two types are equal.
87055. **comment:** Adds a test part result to the list.
 label: test

87056. Creates directories so that path exists. Returns true if successful or if the directories already exist; returns false if unable to create directories for any reason. Will also return false if the FilePath does not represent a directory (that is, it doesn't end with a path separator).
87057. `_WIN32_WCE`
87058. Returns the working directory when the first TEST() or TEST_F() was executed. The UnitTest object owns the string.
87059. An array of TestPartResult objects. Don't inherit from TestPartResultArray as its destructor is not virtual.
87060. Constructor.
87061. Postfix version of operator++.
87062. Type utilities needed for implementing typed and type-parameterized tests. This file is generated by a SCRIPT. DO NOT EDIT BY HAND! Currently we support at most 50 types in a list, and at most 50 type-parameterized tests in one type-parameterized test case. Please contact googletestframework@googlegroups.com if you need more.
87063. Utilities for native arrays.
87064. Fired after the test case ends.
87065. ValuesIn() function allows generation of tests with parameters coming from a container. Synopsis: ValuesIn(const T (&array)[N]) - returns a generator producing sequences with elements from a C-style array. ValuesIn(const Container& container) - returns a generator producing sequences with elements from an STL-style container. ValuesIn(Iterator begin, Iterator end) - returns a generator producing sequences with elements from a range [begin, end) defined by a pair of STL-style iterators. These iterators can also be plain C pointers. Please note that ValuesIn copies the values from the containers passed in and keeps them to generate tests in RUN_ALL_TESTS(). Examples: This instantiates tests from test case StringTest each with C-string values of "foo", "bar", and "baz": const char* strings[] = {"foo", "bar", "baz"}; INSTANTIATE_TEST_CASE_P(StringSequence, SrtngTest, ValuesIn(strings)); This instantiates tests from test case StlStringTest each with STL strings with values "a" and "b": ::std::vector< ::std::string> GetParameterStrings() { ::std::vector< ::std::string> v; v.push_back("a"); v.push_back("b"); return v; } INSTANTIATE_TEST_CASE_P(CharSequence, StlStringTest, ValuesIn(GetParameterStrings())); This will also instantiate tests from CharTest each with parameter values 'a' and 'b': ::std::list<char> GetParameterChars() { ::std::list<char> list; list.push_back('a'); list.push_back('b'); return list; } ::std::list<char> l = GetParameterChars(); INSTANTIATE_TEST_CASE_P(CharSequence2, CharTest, ValuesIn(l.begin(), l.end()));
87066. To avoid conditional compilation everywhere, we make it gtest-port.h's responsibility to #include the header implementing tuple.
87067. Template lists of length 1, 2, 3, and so on.
87068. !defined(GTEST_HAS_STD_STRING)
87069. Returns a copy of the FilePath with the case-insensitive extension removed. Example: FilePath("dir/file.exe").RemoveExtension("EXE") returns FilePath("dir/file"). If a case-insensitive extension is not found, returns a copy of the original FilePath.
87070. The helper class for {ASSERT|EXPECT}_EQ. The template argument `lhs_is_null_literal` is true iff the first argument to ASSERT_EQ() is a null pointer literal. The following default implementation is for `lhs_is_null_literal` being false.
87071. **comment:** INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Outputs a message explaining invalid registration of different fixture class for the same test case. This may happen when TEST_P macro is used to define two tests with the same name but in different namespaces.
label: code-design
87072. Determines whether to support death tests. Google Test does not support death tests for VC 7.1 and earlier as abort() in a VC 7.1 application compiled as GUI in debug config pops up a dialog window that cannot be suppressed programmatically.
87073. This flag sets how many times the tests are repeated. The default value is 1. If the value is -1 the tests are repeating forever.
87074. GTEST_INCLUDE_GTEST_GTEST_MESSAGE_H_ Copyright 2005, Google Inc. All rights reserved. Redistribution and use in source and binary forms, with or without modification, are permitted provided that the following conditions are met: * Redistributions of source code must retain the above copyright notice, this list of conditions and the following disclaimer. * Redistributions in binary form must reproduce the above copyright notice, this list of conditions and the following disclaimer in the documentation and/or other materials provided with the distribution. * Neither the name of Google Inc. nor the names of its contributors may be used to endorse or promote products derived from this software without specific prior written permission. THIS SOFTWARE IS PROVIDED BY THE COPYRIGHT HOLDERS AND CONTRIBUTORS "AS IS" AND ANY EXPRESS OR IMPLIED WARRANTIES, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE ARE DISCLAIMED. IN NO EVENT SHALL THE COPYRIGHT OWNER OR CONTRIBUTORS BE LIABLE FOR ANY DIRECT, INDIRECT, INCIDENTAL, SPECIAL, EXEMPLARY, OR CONSEQUENTIAL DAMAGES (INCLUDING, BUT NOT LIMITED TO, PROCUREMENT OF SUBSTITUTE GOODS OR SERVICES; LOSS OF USE, DATA, OR PROFITS; OR BUSINESS INTERRUPTION) HOWEVER CAUSED AND ON ANY THEORY OF LIABILITY, WHETHER IN CONTRACT, STRICT LIABILITY, OR TORT (INCLUDING NEGLIGENCE OR OTHERWISE) ARISING IN ANY WAY OUT OF THE USE OF THIS SOFTWARE, EVEN IF ADVISED OF THE POSSIBILITY OF SUCH DAMAGE. Authors: wan@google.com (Zhanyong Wan), eefacm@gmail.com (Sean McAfee) The Google C++ Testing Framework (Google Test) This header file declares the String class and functions used internally by Google Test. They are subject to change without notice. They should not be used by code external to Google Test. This header file is #included by <gtest/internal/gtest-internal.h>. It should not be #included by other files.
87075. **comment:** We cannot name this class MutexLock because the ctor declaration would conflict with a macro named MutexLock, which is defined on some platforms. That macro is used as a defensive measure to prevent against inadvertent misuses of MutexLock like "MutexLock(&mu)" rather than "MutexLock l(&mu)". Hence the typedef trick below.
label: code-design
87076. Returns the prefix of 'str' before the first comma in it; returns the entire string if it contains no comma.
87077. Smart pointer members.
87078. Prints the fields of a tuple tersely to a string vector, one element for each field. See the comment before UniversalTersePrint() for how we define "tersely".
87079. Creates a new ValueHolder<T> object holding a default value passed to this ThreadLocal<T>'s constructor and returns it. It is the caller's responsibility not to call this when the ThreadLocal<T> instance already has a value on the current thread.
87080. GTEST_OS_LINUX_ANDROID && __STLPORT_MAJOR && !_EXCEPTIONS
87081. Returns true iff the test part fatally failed.
87082. GTEST_n_TUPLE_(T) is the type of an n-tuple.
87083. Protects mutable state in *impl_. This is mutable as some const methods need to lock it too.
87084. 5-ary predicate assertion macros.
87085. Fired after each iteration of tests finishes.
87086. Returns the bits that represents this number.
87087. GTEST_HAS_STD_TUPLE_
87088. Sleeps for (roughly) n milliseconds. This function is only for testing Google Test's own constructs. Don't use it in user tests, either directly or indirectly.
87089. Adds a reference to const on top of T as necessary. For example, it transforms `char ==> const char&` `const char ==> const char&` `char& ==> const char&` The argument T must depend on some template parameters.
87090. The Nokia Symbian and IBM XL C/C++ compilers cannot decide between `const T&` and `const T*` in a function template. These compilers _can_ decide between class template specializations for T and T*, so a tr1::type_traits-like is_pointer works.
87091. Clang defines __GXX_RTTI starting with version 3.0, but its manual recommends using `has_feature` instead. `has_feature(cxx_rtti)` is supported since 2.7, the first version with C++ support.
87092. Values() allows generating tests from explicitly specified list of parameters. Synopsis: Values(T v1, T v2, ..., T vN) - returns a generator producing sequences with elements v1, v2, ..., vN. For example, this instantiates tests from test case BarTest each with values "one", "two", and "three": INSTANTIATE_TEST_CASE_P(NumSequence, BarTest, Values("one", "two", "three")); This instantiates tests from test case BazTest each with values 1, 2, 3.5. The exact type of values will depend on the type of parameter in BazTest. INSTANTIATE_TEST_CASE_P(FloatingNumbers, BazTest, Values(1, 2, 3.5)); Currently, Values() supports from 1 to 50 parameters.
87093. Creates a TestCase with the given name. TestCase does NOT have a default constructor. Always use this constructor to create a TestCase object. Arguments: name: name of the test case a_type_param: the name of the test's type parameter, or NULL if this is not a type-parameterized test. set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case
87094. We already know that 'expected' is a null pointer.
87095. Internal macro for implementing {EXPECT|ASSERT}_PRED_FORMAT4. Don't use this in your code.
87096. Helper function for implementing {EXPECT|ASSERT}_PRED5. Don't use this in your code.
87097. IsAProtocolMessage<T>::value is a compile-time bool constant that's true iff T is type ProtocolMessage, proto2::Message, or a subclass of those.
87098. Makes a successful assertion result.
87099. is a pointer

87100. GCC 4.5.4

87101. Clones a 0-terminated C string, allocating memory using new. The caller is responsible for deleting the return value using delete[]. Returns the cloned string, or NULL if the input is NULL. This is different from strdup() in string.h, which allocates memory using malloc().

87102. Assignment operator.

87103. **comment:** The current parameter value. Is also available in the test fixture's constructor. This member function is non-static, even though it only references static data, to reduce the opportunity for incorrect uses like writing 'WithParamInterface<bool>::GetParam()' for a test that uses a fixture whose parameter type is int.
label: code-design

87104. The Message class works like an ostream repeater. Typical usage: 1. You stream a bunch of values to a Message object. It will remember the text in a stringstream. 2. Then you stream the Message object to an ostream. This causes the text in the Message to be streamed to the ostream. For example; testing::Message foo; foo << 1 << " != " << 2; std::cout << foo; will print "1 != 2". Message is not intended to be inherited from. In particular, its destructor is not virtual. Note that stringstream behaves differently in gcc and in MSVC. You can stream a NULL char pointer to it in the former, but not in the latter (it causes an access violation if you do). The Message class hides this difference by treating a NULL char pointer as "(null)".

87105. **comment:** Gets the number of disabled tests in this test case.

label: test

87106. On Android, clone() is only available on ARM starting with Gingerbread.

87107. For timespec and nanosleep, used below. NOLINT

87108. MSVC can be configured to define wchar_t as a typedef of unsigned short. It defines _NATIVE_WCHAR_T_DEFINED when wchar_t is a native type. When wchar_t is a typedef, defining an overload for const wchar_t* would cause unsigned short* be printed as a wide string, possibly causing invalid memory accesses.

87109. for param_it for gen_it for test_it RegisterTests

87110. Compares two C strings, ignoring case. Returns true iff they have the same content. Unlike strcasecmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.

87111. Returns the TestResult containing information on test failures and properties logged outside of individual test cases.

87112. Generates a success with a generic message.

87113. Next, recurses (at compile time) with the tail of the test list.

87114. The IEEE standard says that any comparison operation involving a NAN must return false.

87115. Then, use the TEST_P macro to define as many parameterized tests for this fixture as you want. The _P suffix is for "parameterized" or "pattern", whichever you prefer to think.

87116. **comment:** Gets the message associated with the test part.

label: test

87117. Returns true iff the current test has a fatal failure.

87118. Get the number of tests in this test case that should run.

87119. __has_feature(address_sanitizer)

87120. Starting with version 9.0 IBM Visual Age defines __RTTI_ALL__ to 1 if both the typeid and dynamic_cast features are present.

87121. ArrayEq() compares two k-dimensional native arrays using the elements' operator==, where k can be any integer ≥ 0 . When k is 0, ArrayEq() degenerates into comparing a single pair of values.

87122. Restores the test order to before the first shuffle.

87123. 4-ary predicate assertion macros.

87124. T is a function type, so '*os << p' doesn't do what we want (it just prints p as bool). We want to print p as a const void*. However, we cannot cast it to const void* directly, even using reinterpret_cast, as earlier versions of gcc (e.g. 3.4.5) cannot compile the cast when p is a function pointer. Casting to UInt64 first solves the problem.

87125. __WIN32_WCE

87126. Utilities for command line flags and environment variables.

87127. **comment:** The compiler used in Symbian has a bug that prevents us from declaring the tuple template as a friend (it complains that tuple is redefined). This hack bypasses the bug by declaring the members that should otherwise be private as public. Sun Studio versions < 12 also have the above bug.

label: code-design

87128. Windows CE has no C library. The abort() function is used in several places in Google Test. This implementation provides a reasonable imitation of standard behaviour.

87129. !GTEST_LANG_CXX11

87130. Returns true iff the test part failed.

87131. Controls whether events will be forwarded by the repeater to the listeners in the list.

87132. Constructs from a native array. References the source.

87133. Exception handling is in effect by default in HP aCC compiler. It has to be turned off by +noeh compiler option if desired.

87134. **comment:** This helper reduces code bloat. If we instead put its logic inside the previous CopyArray() function, arrays with different sizes would lead to different copies of the template code.

label: code-design

87135. Distinct from C++11 language support, some environments don't provide proper C++11 library support. Notably, it's possible to build in C++11 mode when targeting Mac OS X 10.6, which has an old libstdc++ with no C++11 support. libstdc++ has sufficient C++11 support as of GCC 4.6.0, __GLIBCXX__ 20110325, but maintenance releases in the 4.4 and 4.5 series followed this date, so check for those versions by their date stamps.
<https://gcc.gnu.org/onlinedocs/libstdc++/manual/abi.html#abi.versioning>

87136. Determine whether the compiler supports Microsoft's Structured Exception Handling. This is supported by several Windows compilers but generally does not exist on any other system.

87137. To distinguish different instances of the pattern, (yes, you can instantiate it more than once) the first argument to the INSTANTIATE_TEST_CASE_P macro is a prefix that will be added to the actual test case name. Remember to pick unique prefixes for different instantiations. The tests from the instantiation above will have these names: * InstantiationName/FooTest.DoesBlah/0 for "meeny" * InstantiationName/FooTest.DoesBlah/1 for "miny" * InstantiationName/FooTest.DoesBlah/2 for "moe" * InstantiationName/FooTest.HasBlahBlah/0 for "meeny" * InstantiationName/FooTest.HasBlahBlah/1 for "miny" * InstantiationName/FooTest.HasBlahBlah/2 for "moe" You can use these names in --gtest_filter. This statement will instantiate all tests from FooTest again, each with parameter values "cat" and "dog".

87138. Returns true iff the handle is a valid handle object that can be closed.

87139. First, register the first test in 'Test' for each type in 'Types'.

87140. For selecting which printer to use when a given type has neither << nor PrintTo().

87141. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_FILEPATH_H_ This file was GENERATED by command: pump.py gtest-type-util.h.pump DO NOT EDIT BY HAND!!!

87142. Returns the sign bit of this number.

87143. Tears down the stuff shared by all tests in this test case. Google Test will call Foo::TearDownTestCase() after running the last test in test case Foo. Hence a sub-class can define its own TearDownTestCase() method to shadow the one defined in the super class.

87144. Create a new circle that includes only this instance.

87145. EnableIf<condition>::type is void when 'Cond' is true, and undefined when 'Cond' is false. To use SFINAE to make a function overload only apply when a particular expression is true, add "typename EnableIf<expression>::type* = 0" as the last parameter.

87146. Macros for testing exceptions. * {ASSERT|EXPECT}_THROW(statement, expected_exception): Tests that the statement throws the expected exception. * {ASSERT|EXPECT}_NO_THROW(statement): Tests that the statement doesn't throw any exception. * {ASSERT|EXPECT}_ANY_THROW(statement): Tests that the statement throws an exception.

87147. Used to print a non-container, non-pointer value when the user doesn't define PrintTo() for it.

87148. Defines synchronization primitives.

87149. Returns the string representation of the regex.

87150. If you see an error about overriding the following function or about it being private, you have mis-spelled SetUp() as Setup().

87151. Fired before environment tear-down for each iteration of tests starts.

87152. Implements the helper function for {ASSERT|EXPECT}_GT

87153. A helper for implementing tuple_element<k, T>. kIndexValid is true iff k < the number of fields in tuple type T.

87154. A key pthreads uses for looking up per-thread values.
87155. A protobuf type a type implicitly convertible to BiggestInt (e.g. a named or unnamed enum type) anything else
87156. unit_test
87157. Constructs a Message from a C-string.
87158. class CartesianProductGenerator8::Iterator
87159. Returns the TestPartResult at the given index (0-based).
87160. Creates a new TestInfo object and registers it with Google Test; returns the created object. Arguments: test_case_name: name of the test case name; name of the test type_param the name of the test's type parameter, or NULL if this is not a typed or a type-parameterized test. value_param text representation of the test's value parameter, or NULL if this is not a type-parameterized test. fixture_class_id: ID of the test fixture class set_up_tc: pointer to the function that sets up the test case tear_down_tc: pointer to the function that tears down the test case factory: pointer to the factory that creates a test object. The newly created TestInfo instance will assume ownership of the factory object.
87161. Poor man's downcast.
87162. Flushes the buffers and, if severity is GTEST_FATAL, aborts the program.
87163. Join an existing circle.
87164. Formats log entry severity, provides a stream object for streaming the log message, and terminates the message with a newline when going out of scope.
87165. A pointer to the base generator instance. Used only for the purposes of iterator comparison to make sure that two iterators belong to the same generator.
87166. Base part of test case name for display purposes.
87167. Used to print a pointer that is neither a char pointer nor a member pointer, when the user doesn't define PrintTo() for it. (A member variable pointer or member function pointer doesn't really point to a location in the address space. Their representation is implementation-defined. Therefore they will be printed as raw bytes.)
87168. Cygwin 1.7 and below doesn't support ::std::wstring. Solaris' libc++ doesn't support it either. Android has no support for it at least as recent as Froyo (2.2).
87169. A handy wrapper around AddReference that works when the argument T depends on template parameters.
87170. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_TUPLE_H_
87171. Implements printing a reference type T&.
87172. C-string Comparisons. All tests treat NULL and any non-NULL string as different. Two NULLs are equal. * {ASSERT|EXPECT}_STREQ(s1, s2): Tests that s1 == s2 * {ASSERT|EXPECT}_STRNE(s1, s2): Tests that s1 != s2 * {ASSERT|EXPECT}_STRCASEEQ(s1, s2): Tests that s1 == s2, ignoring case * {ASSERT|EXPECT}_STRCASENE(s1, s2): Tests that s1 != s2, ignoring case For wide or narrow string objects, you can use the {ASSERT|EXPECT}_??() macros. Don't depend on the order in which the arguments are evaluated, which is undefined. These macros evaluate their arguments exactly once.
87173. Since the basic IO manipulators are overloaded for both narrow and wide streams, we have to provide this specialized definition of operator <<, even though its body is the same as the templated version above. Without this definition, streaming endl or other basic IO manipulators to Message will confuse the compiler.
87174. This header implements a family of generic predicate assertion macros: ASSERT_PRED_FORMAT1(pred_format, v1) ASSERT_PRED_FORMAT2(pred_format, v1, v2) ... where pred_format is a function or functor that takes n (in the case of ASSERT_PRED_FORMATn) values and their source expression text, and returns a testing::AssertionResult. See the definition of ASSERT_EQ in gtest.h for an example. If you don't care about formatting, you can use the more restrictive version: ASSERT_PRED1(pred, v1) ASSERT_PRED2(pred, v1, v2) ... where pred is an n-ary function or functor that returns bool, and the values v1, v2, ..., must support the << operator for streaming to std::ostream. We also define the EXPECT_* variations. For now we only support predicates whose arity is at most 5. Please email googletestframework@googlegroups.com if you need support for higher arities.
87175. xLC defines __EXCEPTIONS to 1 iff exceptions are enabled.
87176. class CartesianProductGenerator10::Iterator
87177. **comment:** MSVC defines this macro iff RTTI is enabled.
- label:** code-design
87178. Gets the number of successful tests.
87179. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_TYPE_UTIL_H_
87180. Finds the first element in the iterator range [begin, end) that equals elem. Element may be a native array type itself.
87181. The vector of TestInfos in their original order. It owns the elements in the vector.
87182. Overloads for ::string and ::std::string.
87183. Inspired by http://clang.llvm.org/docs/LanguageExtensions.html#_has_include
87184. unsigned int has size 4 in both gcc and MSVC. As base/basictypes.h doesn't compile on Windows, we cannot use uint32, uint64, and etc here.
87185. Gets the number of failed test cases.
87186. The helper function for {ASSERT|EXPECT}_STRCASENE. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
87187. A copyable object representing a user specified test property which can be output as a key/value string pair. Don't inherit from TestProperty as its destructor is not virtual.
87188. pthread_create() accepts a pointer to a function type with the C linkage. According to the Standard (7.5/1), function types with different linkages are different even if they are otherwise identical. Some compilers (for example, SunStudio) treat them as different types. Since class methods cannot be defined with C-linkage we need to define a free C-function to pass into pthread_create().
87189. test_info
87190. NOLINT !GTEST_HAS_RTTI && GTEST_GCC_VER_ < 40302
87191. **comment:** Feature-indicating macros ----- Macros indicating which Google Test features are available (a macro is defined to 1 if the corresponding feature is supported; otherwise UNDEFINED -- it's never defined to 0.). Google Test defines these macros automatically. Code outside Google Test MUST NOT define them. These macros are public so that portable tests can be written. Such tests typically surround code using a feature with an #if which controls that code. For example: #if GTEST_HAS_DEATH_TEST EXPECT_DEATH(DoSomethingDeadly()); #endif GTEST_HAS_COMBINE - the Combine() function (for value-parameterized tests) GTEST_HAS_DEATH_TEST - death tests GTEST_HAS_PARAM_TEST - value-parameterized tests GTEST_HAS_TYPED_TEST - typed tests GTEST_HAS_TYPED_TEST_P - type-parameterized tests GTEST_IS_THREADSAFE - Google Test is thread-safe. GTEST_USES_POSIX_REGEX - enhanced POSIX regex is used. Do not confuse with GTEST_USES_POSIX_REGEX (see above) which users can define themselves. GTEST_USES_SIMPLE_REGEX - our own simple regex is used; the above two are mutually exclusive. GTEST_CAN_COMPARE_NULL - accepts untyped NULL in EXPECT_EQ().
- label:** code-design
87192. Provides a way for a thread to send notifications to a ThreadLocal regardless of its parameter type.
87193. Signals that the death test did not die as expected.
87194. We cannot call PrintTo(*it, os) here as PrintTo() doesn't handle *it being a native array.
87195. Prefix version of operator++.
87196. Test case base name for display purposes.
87197. Runs TearDownTestCase() for this TestCase. This wrapper is needed for catching exceptions thrown from TearDownTestCase().
87198. Generates a nonfatal failure at the given source file location with a generic message.
87199. Determines whether the given iterator and other point to the same element in the sequence generated by the generator. Used for implementing ParamGenerator<T>::operator==().
87200. **comment:** INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Use ImplicitCast_ as a safe version of static_cast for upcasting in the type hierarchy (e.g. casting a Foo* to a SuperclassOfFoo* or a const Foo*). When you use ImplicitCast_, the compiler checks that the cast is safe. Such explicit ImplicitCast_s are necessary in surprisingly many situations where C++ demands an exact type match instead of an argument type convertible to a target type. The syntax for using ImplicitCast_ is the same as for static_cast: ImplicitCast_<ToType>(expr) ImplicitCast_ would have been part of the C++ standard library, but the proposal was submitted too late. It will probably make its way into the language in the future. This relatively ugly name is intentional. It prevents clashes with similar functions users may have (e.g., implicit_cast). The internal namespace alone is not enough because the function can be found by ADL.
- label:** code-design
87201. Helper function for printing a tuple. Tuple must be either std::tr1::tuple or std::tuple type.
87202. GTEST_INCLUDE_GTEST_GTEST_PRED_IMPL_H_
87203. The value supplied by the user.
87204. MSVC warns about adding const to a function type, so we want to disable the warning.
87205. Creates an empty TestResult.
87206. This file was GENERATED by command: pump.py gtest-tuple.h.pump DO NOT EDIT BY HAND!!!
87207. This is an ordinary non-parameterized test.

87208. Until version 4.3.2, gcc has a bug that causes <tr1/functional>, which is #included by <tr1/tuple>, to not compile when RTTI is disabled. _TR1_FUNCTIONAL is the header guard for <tr1/functional>. Hence the following #define is a hack to prevent <tr1/functional> from being included.

87209. GTEST_HAS_CXXABI_H_ || __HP_aCC

87210. GTEST_HAS_EXCEPTIONS

87211. The specialization for size 4.

87212. **comment:** Prints the given number of elements in an array, without printing the curly braces.
label: code-design

87213. class CartesianProductGenerator3::Iterator

87214. Gets the i-th test case among all the test cases. i can range from 0 to total_test_case_count() - 1. If i is not in that range, returns NULL.

87215. For ::std::pair.

87216. We lose support for NULL detection where the compiler doesn't like passing non-POD classes through ellipsis (...).

87217. User-supplied thread function. User-supplied parameter to the thread function. When non-NULL, used to block execution until the controller thread notifies.

87218. Streams a Message to an ostream.

87219. Helper function for implementing {EXPECT|ASSERT}_PRED2. Don't use this in your code.

87220. Returns the death test count.

87221. UniversalPrintArray(begin, len, os) prints an array of 'len' elements, starting at address 'begin'.

87222. Functions with a different name on Windows.

87223. 0 seconds. And n ms.

87224. MakeFrom() is an expression whose type is From. We cannot simply use From(), as the type From may not have a public default constructor.

87225. TestClass must be a subclass of WithParamInterface<T> and Test.

87226. Internal macro for implementing {EXPECT|ASSERT}_PRED1. Don't use this in your code.

87227. The mask for the sign bit.

87228. Assume that Win32 HANDLE type is equivalent to void*. Doing so allows us to avoid including <windows.h> in this header file. Including <windows.h> is undesirable because it defines a lot of symbols and macros that tend to conflict with client code. This assumption is verified by WindowsTypesTest.HANDLEIsVoidStar.

87229. Always returns false.

87230. Ternary predicate assertion macros.

87231. Mutex implements mutex on Windows platforms. It is used in conjunction with class MutexLock: Mutex mutex; ... MutexLock lock(&mutex); // Acquires the mutex and releases it at the // end of the current scope. A static Mutex *must* be defined or declared using one of the following macros:
GTEST_DEFINE_STATIC_MUTEX_(g_some_mutex); GTEST_DECLARE_STATIC_MUTEX_(g_some_mutex); (A non-static Mutex is defined/declared in the usual way).

87232. Calculate the diff between 'left' and 'right' and return it in unified diff format. If not null, stores in 'total_line_count' the total number of lines found in left + right.

87233. Gets the number of successful tests in this test case.

87234. Note that we call GetTestId() instead of GetTypeId< ::testing::Test>() here to get the type ID of testing::Test. This is to work around a suspected linker bug when using Google Test as a framework on Mac OS X. The bug causes GetTypeId< ::testing::Test>() to return different values depending on whether the call is from the Google Test framework itself or from user test code. GetTestId() is guaranteed to always return the same value, as it always calls GetTypeId<>()

from the Google Test framework.

87235. Returns true iff the unit test failed (i.e. some test case failed or something outside of all tests failed).

87236. Helper function for implementing ASSERT_NEAR. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

87237. Misc public macros ----- GTEST_FLAG(flag_name) - references the variable corresponding to the given Google Test flag.

87238. **comment:** Defines a test that uses a test fixture. The first parameter is the name of the test fixture class, which also doubles as the test case name. The second parameter is the name of the test within the test case. A test fixture class must be declared earlier. The user should put his test code between braces after using this macro. Example: class FooTest : public testing::Test { protected: virtual void SetUp() { b_.AddElement(3); } Foo a_; Foo b_; }; TEST_F(FooTest, InitializesCorrectly) { EXPECT_TRUE(a_.StatusIsOK()); } TEST_F(FooTest, ReturnsElementCountCorrectly) { EXPECT_EQ(0, a_.size()); } EXPECT_EQ(1, b_.size()); }
label: code-design

87239. RTTI: debug mode only!

87240. Adds a TestInfo to this test case. Will delete the TestInfo upon destruction of the TestCase object.

87241. Gets the text streamed to this object so far as an std::string. Each '\0' character in the buffer is replaced with "\\0". INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

87242. The following family of struct and struct templates are used to represent type lists. In particular, TypesN<T1, T2, ..., TN> represents a type list with N types (T1, T2, ..., and TN) in it. Except for Types0, every struct in the family has two member types: Head for the first type in the list, and Tail for the rest of the list.

87243. 0

87244. Gets the name of the TestCase.

87245. Fired before each iteration of tests starts. There may be more than one iteration if GTEST_FLAG(repeat) is set. iteration is the iteration index, starting from 0.

87246. Returns true iff the test has a non-fatal failure.

87247. Sets the default_xml_generator attribute to the provided listener. The listener is also added to the listener list and previous default_xml_generator is removed from it and deleted. The listener can also be NULL in which case it will not be added to the list. Does nothing if the previous and the current listener objects are the same.

87248. Adds a TestProperty to the current TestResult object when invoked from inside a test, to current TestCase's ad_hoc_test_result_ when invoked from SetUpTestCase or TearDownTestCase, or to the global property set when invoked elsewhere. If the result already contains a property with the same key, the value will be updated.

87249. Defines some utility macros.

87250. dummy

87251. This helper class is used by {ASSERT|EXPECT}_NO_FATAL_FAILURE to check if a statement generates new fatal failures. To do so it registers itself as the current test part result reporter. Besides checking if fatal failures were reported, it only delegates the reporting to the former result reporter. The original result reporter is restored in the destructor. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

87252. A convenient wrapper for adding an environment for the test program. You should call this before RUN_ALL_TESTS() is called, probably in main(). If you use gtest_main, you need to call this before main() starts for it to take effect. For example, you can define a global variable like this: testing::Environment* const foo_env = testing::AddGlobalTestEnvironment(new FooEnvironment); However, we strongly recommend you to write your own main() and call AddGlobalTestEnvironment() there, as relying on initialization of global variables makes the code harder to read and may cause problems when you register multiple environments from different translation units and the environments have dependencies among them (remember that the compiler doesn't guarantee the order in which global variables from different translation units are initialized).

87253. Returns the assertion's negation. Used with EXPECT/ASSERT_FALSE.

87254. This header implements typed tests and type-parameterized tests.

87255. Copy an existing linked_ptr<>, adding ourselves to the list of references.

87256. Create the directory so that path exists. Returns true if successful or if the directory already exists; returns false if unable to create the directory for any reason, including if the parent directory does not exist. Not named "CreateDirectory" because that's a macro on Windows.

87257. Adds the given test name to defined_test_names_ and return true if the test case hasn't been registered; otherwise aborts the program.

87258. This overloaded version can be used in Windows programs compiled in UNICODE mode.

87259. AddRef<T>::type is T if T is a reference; otherwise it's T&. This is the same as tr1::add_reference<T>::type.

87260. Converts an integer from the sign-and-magnitude representation to the biased representation. More precisely, let N be 2 to the power of (kBitCount - 1), an integer x is represented by the unsigned number x + N. For instance, -N + 1 (the most negative number representable using sign-and-magnitude) is represented by 1; 0 is represented by N; and N - 1 (the biggest number representable using sign-and-magnitude) is represented by 2N - 1. Read http://en.wikipedia.org/wiki/Signed_number_representations for more details on signed number representations.

87261. Streams a non-pointer value to this object.

87262. TEST_P macro uses AddTestPattern() to record information about a single test in a LocalTestInfo structure. test_case_name is the base name of the test case (without invocation prefix). test_base_name is the name of an individual test without parameter index. For the test SequenceA/FooTest.DoBar/1 FooTest is test case base name and DoBar is test base name.

87263. Determines the version of gcc that is used to compile this.
87264. These two overloads allow streaming a wide C string to a Message using the UTF-8 encoding.
87265. Defines the unsigned integer type that has the same size as the floating point number.
87266. Asserts that a given statement causes the program to exit, either by explicitly exiting with a nonzero exit code or being killed by a signal, and emitting error output that matches regex.
87267. GTEST_INCLUDE_GTEST_INTERNAL_GTEST_PARAM_UTIL_H_ This file was GENERATED by command: pump.py gtest-param-util-generated.h.pump
DO NOT EDIT BY HAND!!!
87268. No implementation - assignment is unsupported.
87269. Clears the test part results.
87270. Sets parameter value. The caller is responsible for making sure the value remains alive and unchanged throughout the current test.
87271. GTEST_HAS_TR1_TUPLE || GTEST_HAS_STD_TUPLE_
87272. Creates a UTF-16 wide string from the given ANSI string, allocating memory using new. The caller is responsible for deleting the return value using delete[]. Returns the wide string, or NULL if the input is NULL. The wide string is created using the ANSI codepage (CP_ACP) to match the behaviour of the ANSI versions of Win32 calls and the C runtime.
87273. Given directory = "dir", base_name = "test", number = 0, extension = "xml", returns "dir/test.xml". If number is greater than zero (e.g., 12), returns "dir/test_12.xml". On Windows platform, uses \ as the separator rather than /.
87274. Boolean assertions. Condition can be either a Boolean expression or an AssertionResult. For more information on how to use AssertionResult with these macros see comments on that class.
87275. Maps a thread to a set of ThreadLocals that have values instantiated on that thread and notifies them when the thread exits. A ThreadLocal instance is expected to persist until all threads it has values on have terminated.
87276. The mask for the exponent bits.
87277. class CartesianProductGenerator9
87278. The upper limit for valid stack trace depths.
87279. true iff we know that the thread function has finished. The native thread object.
87280. Defines the stderr capturer: CaptureStdout - starts capturing stdout. GetCapturedStdout - stops capturing stdout and returns the captured string. CaptureStderr - starts capturing stderr. GetCapturedStderr - stops capturing stderr and returns the captured string.
87281. ImplicitlyConvertible<From, To>::value is a compile-time bool constant that's true iff type From can be implicitly converted to type To.
87282. Inside a test, access the test parameter with the GetParam() method of the TestWithParam<T> class:
87283. **comment:** Prints the given value using the << operator if it has one; otherwise prints the bytes in it. This is what UniversalPrinter<T>::Print() does when PrintTo() is not specialized or overloaded for type T. A user can override this behavior for a class type Foo by defining an overload of PrintTo() in the namespace where Foo is defined. We give the user this option as sometimes defining a << operator for Foo is not desirable (e.g. the coding style may prevent doing it, or there is already a << operator but it doesn't do what the user wants).
label: code-design
87284. Destroys a TestInfo object. This function is not virtual, so don't inherit from TestInfo.
87285. UnitTest class invokes this method to register tests in this test case test cases right before running tests in RUN_ALL_TESTS macro. This method should not be called more than once on any single instance of a ParameterizedTestCaseInfoBase derived class. UnitTest has a guard to prevent from calling this method more than once.
87286. Assuming T is defined in namespace foo, in the next statement, the compiler will consider all of: 1. foo::operator<< (thanks to Koenig look-up), 2. ::operator<< (as the current namespace is enclosed in ::), 3. testing::internal2::operator<< (thanks to the using statement above). The operator<< whose type matches T best will be picked. We deliberately allow #2 to be a candidate, as sometimes it's impossible to define #1 (e.g. when foo is ::std, defining anything in it is undefined behavior unless you are a compiler vendor.).
87287. Constructs a failure message for Boolean assertions such as EXPECT_TRUE.
87288. Returns the floating-point number that represent positive infinity.
87289. forcing value to bool
87290. DefaultPrintTo() is overloaded. The type of its first two arguments determine which version will be picked. If T is an STL-style container, the version for container will be called; if T is a pointer, the pointer version will be called; otherwise the generic version will be called. Note that we check for container types here, prior to we check for protocol message types in our operator<<. The rationale is: For protocol messages, we want to give people a chance to override Google Mock's format by defining a PrintTo() or operator<<. For STL containers, other formats can be incompatible with Google Mock's format for the container elements; therefore we check for container types here to ensure that our format is used. The second argument of DefaultPrintTo() is needed to bypass a bug in Symbian's C++ compiler that prevents it from picking the right overload between: PrintTo(const T& x, ...); PrintTo(T* x, ...);
87291. Does nothing if the current thread holds the mutex. Otherwise, crashes with high probability.
87292. Gets the number of all test parts. This is the sum of the number of successful test parts and the number of failed test parts.
87293. A helper for implementing get<k>().
87294. **comment:** On MinGW, we can have both GTEST_OS_WINDOWS and GTEST_HAS_PTHREAD defined, but we don't want to use MinGW's pthreads implementation, which has conformance problems with some versions of the POSIX standard.
label: code-design
87295. For FullMatch();
87296. A unique type used as the default value for the arguments of class template Types. This allows us to simulate variadic templates (e.g. Types<int>, Type<int, double>, and etc), which C++ doesn't support directly.
87297. Opaque implementation object. This field is never changed once the object is constructed. We don't mark it as const here, as doing so will cause a warning in the constructor of UnitTest. Mutable state in *impl_ is protected by mutex_.
87298. This field is mutable and needs to be reset before running the test for the second time.
87299. defined(GTEST_TUPLE_NAMESPACE_)
87300. __GNUC__
87301. Macros for declaring flags.
87302. Static value used for accessing parameter during a test lifetime.
87303. Typedefs the instances of the FloatingPoint template class that we care to use.
87304. Returns the name of the parameter type, or NULL if this is not a type-parameterized test case.
87305. Implements the helper function for {ASSERT|EXPECT}_LE
87306. Gets the vector of TestProperties.
87307. A string containing a description of the outcome of the last death test.
87308. How many times InitGoogleTest() has been called.
87309. The following list of PrintTo() overloads tells UniversalPrinter<T>::Print() how to print standard types (built-in types, strings, plain arrays, and pointers).
87310. Adds a TestPartResult to the current TestResult object. All Google Test assertion macros (e.g. ASSERT_TRUE, EXPECT_EQ, etc) eventually call this to report their results. The user code should use the assertion macros instead of calling this directly.
87311. An all-mode assert to verify that the given POSIX-style function call returns 0 (indicating success). Known limitation: this doesn't expand to a balanced 'if' statement, so enclose the macro in {} if you need to use it as the only statement in an 'if' branch.
87312. Returns the ParameterizedTestCaseRegistry object used to keep track of value-parameterized tests and instantiate and register them. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
87313. We declare (but don't implement) this to prevent the compiler from implementing the assignment operator.
87314. Macros that test for HRESULT failure and success, these are only useful on Windows, and rely on Windows SDK macros and APIs to compile. * {ASSERT|EXPECT}_HRESULT_{SUCCEEDED|FAILED}(expr) When expr unexpectedly fails or succeeds, Google Test prints the expected result and the actual result with both a human-readable string representation of the error, if available, as well as the hex result code.
87315. Assignment releases the old value and acquires the new.
87316. Clears the results of all tests in the given test case.
87317. Per <http://blogs.msdn.com/b/oldnewthing/archive/2004/02/23/78395.aspx>, we assume that 0 is an invalid value for thread IDs.
87318. In describing the results of death tests, these terms are used with the corresponding definitions: exit status: The integer exit information in the format specified by wait(2) exit code: The integer code passed to exit(3), _exit(2), or returned from main()

87319. __has_feature(memory_sanitizer)
87320. To refer to typedefs in the fixture, add the "typename TestFixture::" prefix.
87321. GTEST_HAS_CXXABI_H
87322. signed/unsigned char is often used for representing binary data, so we print pointers to it as void* to be safe.
87323. MSVC 2005 and above support variadic macros.
87324. Defines and statically (i.e. at link time) initializes a static mutex. The initialization list here does not explicitly initialize each field, instead relying on default initialization for the unspecified fields. In particular, the owner_field (a pthread_t) is not explicitly initialized. This allows initialization to work whether pthread_t is a scalar or struct. The flag -Wmissing-field-initializers must not be specified for this to work.
87325. Overloaded PrintTo() for tuples of various arities. We support tuples of up-to 10 fields. The following implementation works regardless of whether tr1::tuple is implemented using the non-standard variadic template feature or not.
87326. class CartesianProductGenerator7
87327. This flag brings the debugger on an assertion failure.
87328. Returns the list of event listeners that can be used to track events inside Google Test.
87329. __LIBCPP_VERSION is defined by the libc++ library from the LLVM project.
87330. Looks up or creates and returns a structure containing information about tests and instantiations of a particular test case.
87331. GTEST_HAS_PARAM_TEST
87332. class CartesianProductGenerator6
87333. 1600 is Visual Studio 2010
87334. SameSizeTuplePrefixComparator<k, k>::Eq(t1, t2) returns true if the first k fields of t1 equals the first k fields of t2. SameSizeTuplePrefixComparator(k1, k2) would be a compiler error if k1 != k2.
87335. Test case id to verify identity.
87336. Gets the number of tests to be printed in the XML report.
87337. scripts/fuse_gtest.py depends on gtest's own header being #included *unconditionally*. Therefore these #includes cannot be moved inside #if GTEST_HAS_PARAM_TEST. Copyright 2008 Google Inc. Author: vladl@google.com (Vlad Losev)
87338. Returns true if the death test passed; that is, the test process exited during the test, its exit status matches a user-supplied predicate, and its stderr output matches a user-supplied regular expression. The user-supplied predicate may be a macro expression rather than a function pointer or functor, or else Wait and Passed could be combined.
87339. C++11 specifies that <tuple> provides std::tuple. Use that if gtest is used in C++11 mode and libstdc++ isn't very old (binaries targeting OS X 10.6 can build with clang but need to use gcc4.2's libstdc++).
87340. Returns true iff test passed.
87341. Removes the given event listener from the list and returns it. It then becomes the caller's responsibility to delete the listener. Returns NULL if the listener is not found in the list.
87342. Internal macro for implementing {EXPECT|ASSERT}_PRED_FORMAT5. Don't use this in your code.
87343. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.
87344. For all other compilers, we assume RTTI is enabled.
87345. class CartesianProductGenerator6::Iterator
87346. Makes sure this header is not included before gtest.h.
87347. GTEST_HAS_SEH
87348. On Symbian, BOOST_HAS_TR1_TUPLE causes Boost's TR1 tuple library to use STLport's tuple implementation, which unfortunately doesn't work as the copy of STLport distributed with Symbian is incomplete. By making sure BOOST_HAS_TR1_TUPLE is undefined, we force Boost to use its own tuple implementation.
87349. We disallow copying TestEventListeners.
87350. Implements a subset of TR1 tuple needed by Google Test and Google Mock.
87351. Static utility methods
87352. This file is AUTOMATICALLY GENERATED on 10/31/2011 by command 'gen_gtest_pred_impl.py 5'. DO NOT EDIT BY HAND! Implements a family of generic predicate assertion macros.
87353. Helper function for implementing {EXPECT|ASSERT}_PRED1. Don't use this in your code.
87354. case_name
87355. # of exponent bits in a number.
87356. Returns the number of TestPartResult objects in the array.
87357. class CartesianProductHolder8
87358. GTEST_INCLUDE_GTEST_GTEST_DEATH_TEST_H_ This file was GENERATED by command: pump.py gtest-param-test.h.pump DO NOT EDIT BY HAND!!!
87359. **comment:** If the array has more than kThreshold elements, we'll have to omit some details by printing only the first and the last kChunkSize elements.
TODO(wan@google.com): let the user control the threshold using a flag.
label: code-design
87360. The index for the end() iterator. All the elements in the generated sequence are indexed (0-based) to aid iterator comparison.
87361. The d'tor pops the info pushed by the c'tor. Note that the d'tor is not virtual in order to be efficient. Don't inherit from ScopedTrace!
87362. We disallow copying TestResult.
87363. Constants.
87364. Prints the first N fields of a tuple.
87365. This templated version is for the general case.
87366. The GTEST_COMPILE_ASSERT_ macro can be used to verify that a compile time expression is true. For example, you could use it to verify the size of a static array: GTEST_COMPILE_ASSERT_(GTEST_ARRAY_SIZE_(names) == NUM_NAMES, names_incorrect_size); or to make sure a struct is smaller than a certain size: GTEST_COMPILE_ASSERT_(sizeof(foo) < 128, foo_too_large); The second argument to the macro is the name of the variable. If the expression is false, most compilers will issue a warning/error containing the name of the variable.
87367. Inside a test, refer to TypeParam to get the type parameter. Since we are inside a derived class template, C++ requires use to visit the members of FooTest via 'this'.
87368. Evaluates to the number of elements in 'array'.
87369. This exception is thrown by (and only by) a failed Google Test assertion when GTEST_FLAG(throw_on_failure) is true (if exceptions are enabled). We derive it from std::runtime_error, which is for errors presumably detectable only at run time. Since std::runtime_error inherits from std::exception, many testing frameworks know how to extract and print the message inside it.
87370. other_operand
87371. Finally, you can use INSTANTIATE_TEST_CASE_P to instantiate the test case with any set of parameters you want. Google Test defines a number of functions for generating test parameters. They return what we call (surprise!) parameter generators. Here is a summary of them, which are all in the testing namespace:
Range(begin, end [, step]) - Yields values {begin, begin+step, begin+2*step, ...}. The values do not include end. step defaults to 1. Values(v1, v2, ..., vN) - Yields values {v1, v2, ..., vN}. ValuesIn(container) - Yields values from a C-style array, an STL ValuesIn(begin,end) container, or an iterator range [begin, end).
Bool() - Yields sequence {false, true}. Combine(g1, g2, ..., gN) - Yields all combinations (the Cartesian product for the math savvy) of the values generated by the

N generators. For more details, see comments at the definitions of these functions below in this file. The following statement will instantiate tests from the FooTest test case each with parameter values "meeny", "miny", and "moe".

87372. First, registers the first type-parameterized test in the type list.

87373. Returns a Boolean value indicating whether the caller is currently executing in the context of the death test child process. Tools such as Valgrind heap checkers may need this to modify their behavior in death tests. IMPORTANT: This is an internal utility. Using it may break the implementation of death tests. User code MUST NOT use it.

87374. Forward declarations.

87375. **comment:** Traps C++ exceptions escaping statement and reports them as test failures. Note that trapping SEH exceptions is not implemented here.

label: code-design

87376. Creates a test instance to run. The instance is both created and destroyed within TestInfoImpl::Run()

87377. Causes a trace (including the source file path, the current line number, and the given message) to be included in every test failure message generated by code in the current scope. The effect is undone when the control leaves the current scope. The message argument can be anything streamable to std::ostream. In the implementation, we include the current line number as part of the dummy variable name, thus allowing multiple SCOPED_TRACE()s to appear in the same block - as long as they are on different lines.

87378. Implements type-parameterized tests.

87379. Internal macro for implementing {EXPECT|ASSERT}_PRED_FORMAT2. Don't use this in your code.

87380. Functions producing parameter generators. Google Test uses these generators to produce parameters for value- parameterized tests. When a parameterized test case is instantiated with a particular generator, Google Test creates and runs tests for each element in the sequence produced by the generator. In the following sample, tests from test case FooTest are instantiated each three times with parameter values 3, 5, and 8: class FooTest : public TestWithParam<int> { ... }; TEST_P(FooTest, TestThis) { } TEST_P(FooTest, TestThat) { } INSTANTIATE_TEST_CASE_P(TestSequence, FooTest, Values(3, 5, 8));

87381. The interface for tracing execution of tests. The methods are organized in the order the corresponding events are fired.

87382. These are needed as the Nokia Symbian Compiler cannot decide between const T& and const T* in a function template. The Nokia compiler _can_ decide between class template specializations for T and T*, so a tr1::type_traits-like is_pointer works, and we can overload on that.

87383. These classes and functions are friends as they need to access private members of UnitTest.

87384. **comment:** Environment-describing macros ----- Google Test can be used in many different environments. Macros in this section tell Google Test what kind of environment it is being used in, such that Google Test can provide environment-specific features and implementations. Google Test tries to automatically detect the properties of its environment, so users usually don't need to worry about these macros. However, the automatic detection is not perfect. Sometimes it's necessary for a user to define some of the following macros in the build script to override Google Test's decisions. If the user doesn't define a macro in the list, Google Test will provide a default definition. After this header is #included, all macros in this list will be defined to either 1 or 0. Notes to maintainers: - Each macro here is a user-tweakable knob; do not grow the list lightly. - Use #if to key off these macros. Don't use #ifdef or "#if defined(...)", which will not work as these macros are ALWAYS defined. GTEST_HAS_CLONE - Define it to 1/0 to indicate that clone(2) is/isn't available. GTEST_HAS_EXCEPTIONS - Define it to 1/0 to indicate that exceptions are enabled. GTEST_HAS_GLOBAL_STRING - Define it to 1/0 to indicate that ::string is/isn't available (some systems define ::string, which is different to std::string). GTEST_HAS_GLOBAL_WSTRING - Define it to 1/0 to indicate that ::wstring is/isn't available (some systems define ::wstring, which is different to std::wstring). GTEST_HAS_POSIX_REGEX - Define it to 1/0 to indicate that POSIX regular expressions are/aren't available. GTEST_HAS_PTHREAD - Define it to 1/0 to indicate that <pthread.h> is/isn't available. GTEST_HAS_RTTI - Define it to 1/0 to indicate that RTTI is/isn't enabled. GTEST_HAS_STD_WSTRING - Define it to 1/0 to indicate that std::wstring does/doesn't work (Google Test can be used where std::wstring is unavailable). GTEST_HAS_TR1_TUPLE - Define it to 1/0 to indicate tr1::tuple is/isn't available. GTEST_HAS_SEH - Define it to 1/0 to indicate whether the compiler supports Microsoft's "Structured Exception Handling". GTEST_HAS_STREAM_REDIRECTION - Define it to 1/0 to indicate whether the platform supports I/O stream redirection using dup() and dup2(). GTEST_USE_OWN_TR1_TUPLE - Define it to 1/0 to indicate whether Google Test's own tr1 tuple implementation should be used. Unused when the user sets GTEST_HAS_TR1_TUPLE to 0. GTEST_LANG_CXX11 - Define it to 1/0 to indicate that Google Test is building in C++11/C++98 mode. GTEST_LINKED_AS_SHARED_LIBRARY - Define to 1 when compiling tests that use Google Test as a shared library (known as DLL on Windows). GTEST_CREATE_SHARED_LIBRARY - Define to 1 when compiling Google Test itself as a shared library.

label: code-design

87385. Formats an int value as "%02d". "%02d" for width == 2

87386. Blocks until the controller thread notifies. Must be called from a test thread.

87387. **comment:** MSVC "deprecates" snprintf and issues warnings wherever it is used. In order to avoid these warnings, we need to use _snprintf or _snprintf_s on MSVC-based platforms. We map the GTEST_SNPRINTF_ macro to the appropriate function in order to achieve that. We use macro definition here because snprintf is a variadic function.

label: code-design

87388. It's this header's responsibility to #include <typeinfo> when RTTI is enabled.

87389. GTEST_OS_WINDOWS_MOBILE

87390. string.h is not guaranteed to provide strcpy on C++ Builder.

87391. index

87392. Windows CE does not have the 'ANSI' versions of Win32 APIs. To be able to pass strings to Win32 APIs on CE we need to convert them to 'Unicode', UTF-16.

87393. Compares two C strings. Returns true iff they have the same content. Unlike strcmp(), this function can handle NULL argument(s). A NULL C string is considered different to any non-NULL C string, including the empty string.

87394. Verifies that registered_tests match the test names in defined_test_names_; returns registered_tests if successful, or aborts the program otherwise.

87395. it

87396. This flag causes the Google Test to list tests. None of the tests listed are actually run if the flag is provided.

87397. Generates values from a pair of STL-style iterators. Used in the ValuesIn() function. The elements are copied from the source range since the source can be located on the stack, and the generator is likely to persist beyond that stack frame.

87398. Macros for testing equalities and inequalities. * {ASSERT|EXPECT}_EQ(expected, actual): Tests that expected == actual * {ASSERT|EXPECT}_NE(v1, v2): Tests that v1 != v2 * {ASSERT|EXPECT}_LT(v1, v2): Tests that v1 < v2 * {ASSERT|EXPECT}_LE(v1, v2): Tests that v1 <= v2 * {ASSERT|EXPECT}_GT(v1, v2): Tests that v1 > v2 * {ASSERT|EXPECT}_GE(v1, v2): Tests that v1 >= v2 When they are not, Google Test prints both the tested expressions and their actual values. The values must be compatible built-in types, or you will get a compiler error. By "compatible" we mean that the values can be compared by the respective operator. Note: 1. It is possible to make a user-defined type work with {ASSERT|EXPECT}_??(), but that requires overloading the comparison operators and is thus discouraged by the Google C++ Usage Guide. Therefore, you are advised to use the {ASSERT|EXPECT}_TRUE() macro to assert that two objects are equal. 2. The {ASSERT|EXPECT}_??() macros do pointer comparisons on pointers (in particular, C strings). Therefore, if you use it with two C strings, you are testing how their locations in memory are related, not how their content is related. To compare two C strings by content, use {ASSERT|EXPECT}_STR*(). 3.

{ASSERT|EXPECT}_EQ(expected, actual) is preferred to {ASSERT|EXPECT}_TRUE(expected == actual), as the former tells you what the actual value is when it fails, and similarly for the other comparisons. 4. Do not depend on the order in which {ASSERT|EXPECT}_??() evaluate their arguments, which is undefined. 5. These macros evaluate their arguments exactly once. Examples: EXPECT_NE(5, Foo()); EXPECT_EQ(NULL, a_pointer); ASSERT_LT(i, array_size); ASSERT_GT(records.size(), 0) << "There is no record left.";

87399. Information about a trace point. Implements scoped trace. Opaque implementation of TestInfo Opaque implementation of UnitTest

87400. Always returns true.

87401. Copy constructor. NOLINT

87402. ParamType and GeneratorCreationFunc are private types but are required for declarations of public methods AddTestPattern() and AddTestCaseInstantiation().

87403. MSVC 8.0, Sun C++, and IBM XL C++ have a bug which causes the above definition to fail to remove the const in 'const int[3]' and 'const char[3][4]'. The following specialization works around the bug.

87404. is not a pointer

87405. GTEST_HAS_TYPED_TEST

87406. Tests that an exit code describes an exit due to termination by a given signal.

87407. Streams a pointer value to this object. This function is an overload of the previous one. When you stream a pointer to a Message, this definition will be used as it is more specialized. (The C++ Standard, section [temp.func.order].) If you stream a non-pointer, then the previous definition will be used. The reason for this overload is that streaming a NULL pointer to ostream is undefined behavior. Depending on the compiler, you may get "0", "(nil)", "(null)", or an access violation. To ensure consistent result across compilers, we always treat NULL as "(null)".

87408. Then, use TYPED_TEST() instead of TEST_F() to define as many typed tests for this test case as you want.

87409. INTERNAL IMPLEMENTATION - DO NOT USE IN USER CODE. Expands to the name of the variable used to remember the names of the defined tests in the given test case.

87410. TypeParameterizedTestCase<Fixture, Tests, Types>::Register() registers *all combinations* of 'Tests' and 'Types' with Google Test. The return value is insignificant - we just need to return something such that we can call this function in a namespace scope.

87411. Adds reference to a type if it is not a reference type, otherwise leaves it unchanged. This is the same as tr1::add_reference, which is not widely available yet.

87412. Appends the user-supplied message to the Google-Test-generated message.

87413. With the following statement, during unqualified name lookup, testing::internal2::operator<< appears as if it was declared in the nearest enclosing namespace that contains both ::testing_internal and ::testing::internal2, i.e. the global namespace. For more details, refer to the C++ Standard section 7.3.4-1 [namespace.udir]. This allows us to fall back onto testing::internal2::operator<< in case T doesn't come with a << operator. We cannot write 'using ::testing::internal2::operator<<;', which gcc 3.3 fails to compile due to a compiler bug. NOLINT

87414. Overloads for various char types.

87415. Overload for C arrays. Multi-dimensional arrays are printed properly.

87416. class CartesianProductGenerator5::Iterator

87417. isspace(int ch) and friends accept an unsigned char or EOF. char may be signed, depending on the compiler (or compiler flags). Therefore we need to cast a char to unsigned char before calling isspace(), etc.

87418. You can inherit all the usual members for a non-parameterized test fixture here.

87419. An enumeration of possible roles that may be taken when a death test is encountered. EXECUTE means that the death test logic should be executed immediately. OVERSEE means that the program should prepare the appropriate environment for a child process to execute the death test, then wait for it to complete.

87420. Gets the name of the source file where the test part took place, or NULL if it's unknown.

87421. t1

87422. Macros for comparing floating-point numbers. * {ASSERT|EXPECT}_FLOAT_EQ(expected, actual): Tests that two float values are almost equal. * {ASSERT|EXPECT}_DOUBLE_EQ(expected, actual): Tests that two double values are almost equal. * {ASSERT|EXPECT}_NEAR(v1, v2, abs_error): Tests that v1 and v2 are within the given distance to each other. Google Test uses ULP-based comparison to automatically pick a default error bound that is appropriate for the operands. See the FloatingPoint template class in gtest-internal.h if you are interested in the implementation details.

87423. Macro for referencing flags.

87424. **comment:** Even though we don't use this macro any longer, we keep it in case some clients still depend on it.
label: code-design

87425. Runs all tests in this UnitTest object and prints the result. Returns 0 if successful, or 1 otherwise. This method can only be called from the main thread. INTERNAL IMPLEMENTATION - DO NOT USE IN A USER PROGRAM.

87426. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. Default: "\$TEST_PATH/current_time" REMOTE_USER_AT_HOST: If set, then test will run on the specified host under TEST_PATH directory and outputs test results locally in RESULT_PATH The REMOTE_USER_AT_HOST should follow the format user-id@host.name DB_PATH: the path where the rocksdb database will be created during the regression test. Default: \$TEST_PATH/db WAL_PATH: the path where the rocksdb WAL will be outputed. Default: \$TEST_PATH/wal OPTIONS_FILE: If specified, then the regression test will use the specified file to initialize the RocksDB options in its benchmarks. Note that this feature only work for commits after 88acd93 or rocksdb version later than 4.9. DELETE_TEST_PATH: If true, then the test directory will be deleted after the script ends. Default: 0 = db_bench parameters = NUM_THREADS: The number of concurrent foreground threads that will issue database operations in the benchmark. Default: 16. NUM_KEYS: The key range that will be used in the entire regression test. Default: 1G. NUM_OPS: The number of operations (reads, writes, or deletes) that will be issued in EACH thread. Default: \$NUM_KEYS / \$NUM_THREADS KEY_SIZE: The size of each key in bytes in db_bench. Default: 100. VALUE_SIZE: The size of each value in bytes in db_bench. Default: 900. CACHE_SIZE: The size of RocksDB block cache used in db_bench. Default: 1G STATISTICS: If 1, then statistics is on in db_bench. Default: 0. COMPRESSION_RATIO: The compression ratio of the key generated in db_bench. Default: 0.5. HISTOGRAM: If 1, then the histogram feature on performance feature is on. STATS_PER_INTERVAL: If 1, then the statistics will be reported for every STATS_INTERVAL_SECONDS seconds. Default 1. STATS_INTERVAL_SECONDS: If STATS_PER_INTERVAL is set to 1, then statistics will be reported for every STATS_INTERVAL_SECONDS. Default 60. MAX_BACKGROUND_FLUSHES: The maximum number of concurrent flushes in db_bench. Default: 4. MAX_BACKGROUND_COMPACTION: The maximum number of concurrent compactions in db_bench. Default: 16. SEEK_NEXTS: Controls how many Next() will be called after seek. Default: 10. SEED: random seed that controls the randomness of the benchmark. Default: \$(date +%s)

label: code-design

87566. Test the ability to roll by size

87567. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).

87568. **comment:** Since rotation is checked before actual logging, we need to trigger the rotation by logging another message.

label: code-design

87569. **comment:** Replace all slashes in the path so windows CompSpec does not become confused

label: code-design

87570. roll by both Time and size

87571. db_log_dir=

87572. **comment:** an extra-scope to force the AutoRollLogger to flush the log file when it becomes out of scope.

label: code-design

87573. Test the ability to roll by Time

87574. Test the logger Header function for roll over logs We expect the new logs creates as roll over to carry the headers specified

87575. verify that the old log contains all the header logs

87576. Test the cases when the log file will not be rolled.

87577. verify that the files rolled over

87578. Only roll by Time

87579. **comment:** In this test we only want to Log some simple log message with no format. LogMessage() provides such a simple interface and avoids the [format-security] warning which occurs when you call ROCKS_LOG_INFO(logger, log_message) directly.

label: code-design

87580. -- Write to the log for several times, which is supposed to be finished before time.

87581. **comment:** WORKAROUND: avoid compiler's complaint of "comparison between signed and unsigned integer expressions" because literal 0 is treated as "singed".

label: code-design

87582. Notes: (1) Need to pin the old logger before beginning the roll, as rolling grabs the mutex, which would prevent us from accessing the old logger. This also marks flush_thread with AutoRollLogger::Flush::PinnedLogger. (2) Need to reset logger during PosixLogger::Flush() to exercise a race condition case, which is executing the flush with the pinned (old) logger after auto-roll logger has cut over to a new logger. (3) PosixLogger::Flush() happens in both threads but its SyncPoints only are enabled in flush_thread (the one pinning the old logger).

87583. We know that the old log files are named [path]<something>. Return all entities that match the pattern

87584. log messages with log level smaller than log_level will not be logged.

87585. test_num == 0 -> standard call to Header() test_num == 1 -> call to Log() with InfoLogLevel::HEADER_LEVEL

87586. At this time, the new log file should be created.

87587. We run same operations for kOps times in order to get a more fair result.

87588. **comment:** This test case only reports the performance between std::vector<std::string> and autovector<std::string>. We chose string for comparison because in most of our use cases we used std::vector<std::string>.

label: code-design

87589. **comment:** Creation and insertion test Test the case when there is: * no element inserted: internal array of std::vector may not really get initialized. * one element inserted: internal array of std::vector must have initialized. * kSize elements inserted. This shows the most time we'll spend if we keep everything in stack. * 2 * kSize elements inserted. The internal vector of autovector must have been initialized.

87757. Return a random key with the specified length that may contain interesting characters (e.g. \x00, \xff, etc.).

87758. A test comparator which compare two strings in this way: (1) first compare prefix of 8 bytes in alphabet order, (2) if two strings share the same prefix, sort the other part of the string in the reverse alphabet order. This helps simulate the case of compounded key of [entity][timestamp] and latest timestamp first.

87759. The following text is boilerplate that forwards all methods to target()

87760. A dummy merge operator which can change its name

87761. namespace test namespace rocksdb

87762. An internal comparator that just forward comparing results from the user comparator in it. Can be used to test entities that have no dependency on internal key structure but consumes InternalKeyComparator, like BlockBasedTable.

87763. Returns a dummy merge operator with random name.

87764. Iterator over a vector of keys/values

87765. A wrapper around a StringSink to give it a RandomRWFile interface

87766. Like StringSink, this writes into a string. Unlink StringSink, it has some initial content and overwrites it, just like a recycled log file.

87767. **comment:** TODO(yhchiang): Currently doesn't handle the overflow case.

label: code-design

87768. A wrapper that allows injection of errors.

87769. Signalled when background work finishes

87770. Store in *dst a string of length "len" that will compress to "N*compressed_fraction" bytes and return a Slice that references the generated data.

87771. Randomly initialize the given DBOptions

87772. Randomly initialize the given ColumnFamilyOptions Note that the caller is responsible for releasing non-null cf_opt->compaction_filter.

87773. Store in *dst a random string of length "len" and return a Slice that references the generated data.

87774. A dummy compaction filter factory which can change its name

87775. Returns a name that identifies this compaction filter factory.

87776. Filters merge operands and values that are equal to `num`.

87777. Corrupts key by changing the type

87778. Returns a dummy compaction filter with a random name.

87779. **comment:** Returns a user key comparator that can be used for comparing two uint64_t slices. Instead of comparing slices byte-wise, it compares all the 8 bytes at once. Assumes same endian-ness is used though the database's lifetime. Symantics of comparison would differ from Bytewise comparator in little endian machines.

label: code-design

87780. A dummy compaction filter which can change its name

87781. Verify none of the threads are running

87782. simulated tasks

87783. ROCKSDB_USING_THREAD_STATUS

87784. terminate compaction-write tasks and see if the thread-status reflects this update

87785. verify the global tables for operations and states are properly indexed.

87786. schedule the simulated tasks

87787. terminate compaction-wait tasks and see if the thread-status reflects this update

87788. setup right answers

87789. terminate flush-write tasks and see if the thread-status reflects this update

87790. namespace

87848. key format: [SET#][random#]
87849. Non-optimistic transactions should only fail due to expiration or write failures. For testing purposes, we do not expect any write failures.
87850. For each set, pick a key at random and increment it
87851. return success if we didn't get any unexpected errors
87852. Optimistic transactions can have write-conflict errors on commit. Any other error is unexpected.
87853. For each set of keys with the same prefix, sum all the values
87854. ROCKSDB_LITE
87855. stop when we reach a different prefix
87856. prefix_buf needs to be large enough to hold a uint16 in string form
87857. Found key, parse its value
87858. Optimistic transactions should never return non-ok status here. Non-optimistic transactions may return write-conflict/timeout errors.
87859. Since we did a GetForUpdate, Put should not fail.
87860. Pad prefix appropriately so we can iterate over each set
87861. pick a random number to use to increment a key in each set
87862. Increment key
87863. Returns the number of successfully written calls to TransactionDBInsert/OptimisticTransactionDBInsert/DBInsert
87864. Returns the number of calls to TransactionDBInsert/OptimisticTransactionDBInsert/DBInsert that did not write any data.
87865. Number of successful insert batches performed
87866. Increment a key in each set without using a transaction. If this function is called in parallel, then Verify() may fail. Returns true if the write succeeds. Error status may be obtained by calling GetLastStatus().
87867. optimization: re-use allocated transaction objects.
87868. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).

87869. Returns OK if Invariant is true.
87870. Increment a key in each set using a Transaction on a TransactionDB. Returns true if the transaction succeeded OR if any error encountered was expected (eg a write-conflict). Error status may be obtained by calling GetLastStatus();
87871. Utility class for stress testing transactions. Can be used to write many transactions in parallel and then validate that the data written is logically consistent. This class assumes the input DB is initially empty. Each call to TransactionDBInsert() / OptimisticTransactionDBInsert() will increment the value of a key in #num_sets sets of keys. Regardless of whether the transaction succeeds, the total sum of values of keys in each set is an invariant that should remain equal. After calling TransactionDBInsert() / OptimisticTransactionDBInsert() many times, Verify() can be called to validate that the invariant holds. To test writing Transaction in parallel, multiple threads can create a RandomTransactionInserter with similar arguments using the same DB.
87872. Input options
87873. Returns the status of the previous Insert operation
87874. Status returned by most recent insert operation
87875. ROCKSDB_LITE
87876. Number of failed insert batches attempted
87877. namespace rocksdb
87878. Increment a key in each set using a Transaction on an OptimisticTransactionDB Returns true if the transaction succeeded OR if any error encountered was expected (eg a write-conflict). Error status may be obtained by calling GetLastStatus();
87879. num_keys is the number of keys in each set. num_sets is the number of sets of keys.
87880. Read from meta-file failure
87881. test various kind of corruptions that may happen: 1. Not able to write a file for backup - that backup should fail, everything else should work 2. Corrupted backup meta file or missing backedup file - we should not be able to open that backup, but all other backups should be fine 3. Corrupted checksum value - if the checksum is not a valid uint32_t, db open should fail, otherwise, it aborts during the restore process.
87882. should write 5 DB files + one meta file
87883. implicit
87884. pair<filename, alive?>
87885. test purge old backups when i == 4, purge to only 1 backup when i == 3, purge to 2 backups
87886. Verify manifest can roll while a backup is being created with the old manifest.
87887. set up backup db options
87888. set share_files_with_checksum to true and do some more backups
87889. has to be a big number, so that it triggers the memtable flush
87890. what business do you have calling this method?
87891. create backups 1, 2, 3, 4, 5
87892. Backup the LATEST options file to "<backup_dir>/private/<backup_id>/OPTIONS<number>"
87893. files
87894. 1GB
87895. Test that we properly propagate Env failures
87896. namespace rocksdb
87897. MANIFEST file size should be only 100
87898. The last manifest roll would've already been cleaned up by the full scan that happens when CreateNewBackup invokes EnableFileDeletions. We need to trigger another roll to verify non-full scan purges stale manifests.
87899. ----- case 2. corrupted backup meta or missing backedup file -----
87900. 128KB
87901. backup overwrites file 000007.sst
87902. delete old data
87903. utility functions
87904. ----- case 3. - corrupt a file -----
87905. Verify the specified max backups are opened, including skipping over corrupted backups. Setup: - backups 1, 2, and 4 are valid - backup 3 is corrupt - max_valid_backups_to_open == 2 Expectation: the engine opens backups 4 and 2 since those are latest two non-corrupt backups.
87906. now, the backup can succeed
87907. should never get here
87908. no failure

87912. ---- restore the DB ----
87913. TestEnv
87914. new backup should be 2!
87915. this will make sure that backup does not copy the same file twice
87916. checksum of backup 3 is an invalid value, this can be detected at db open time, and it reverts to the previous backup automatically
87917. This test verifies that the verifyBackup method correctly identifies invalid backups
87918. Create logger
87919. 00011.sst was only in backup 1, should be deleted
87920. delete old files in db
87921. should write 4 new DB files + one meta file should not write/copy 00010.sst, since it's already there!
87922. make sure that no corrupt backups have actually been deleted!
87923. To avoid FlushWAL called on stacked db which is nullptr
87924. ----- case 1. - valid backup -----
87925. size_bytes
87926. we should get consistent results with flush_before_backup set to both true and false
87927. open DB, write, backup, write, backup, close, restore
87928. Verify that you can backup and restore with share_files_with_checksum on
87929. should not open 00010.sst - it's already there
87930. logger_ must be above backup_engine_ such that the engine's destructor, which uses a raw pointer to the logger, executes first.
87931. set share_files_with_checksum to false
87932. all the dbs! BackupableDB owns dummy_db_
87933. ----- case 4. - invalid backup -----
87934. destroy_old_data
87935. checksum of the backup 2 appears to be valid, this can cause checksum mismatch and abort restore process
87936. every iteration -- 1. insert new data in the DB 2. backup the DB 3. destroy the db 4. restore the db, check everything is still there
87937. should fail creation
87938. 4 is corrupted, 3 is the latest backup now
87939. in last iteration, put smaller amount of data,
87940. latest backup should have all the keys
87941. Interrupt backup creation by failing new writes and failing cleanup of the partial state. Then verify a subsequent backup can still succeed.
87942. we deleted backup 2
87943. DummyDB
87944. delete backup number 2, online delete!

87945. create five backups
87946. single digit value, safe to insert one more digit
87947. check backup 5
87948. DummyLogFile
87949. Verify that you can backup and restore using share_files_with_checksum set to false and then transition this option to true
87950. close and destroy
87951. anon namespace
87952. Must reset() before reset(OpenDB()) again. Calling OpenDB() while *db_ is existing will cause LOCK issue
87953. first iter -- flush before backup second iter -- don't flush before backup
87954. ----- case 1. - fail a write ----- try creating backup 6, but fail a write
87955. ----- case 3. corrupted checksum value ----
87956. restores backup backup_id and asserts the existence of [start_exist, end_exist] and not-existence of [end_exist, end> if backup_id == 0, it means restore from latest if end == 0, don't check AssertEmpty
87957. delete the corrupt backups and then make sure they're actually deleted
87958. should fail
87959. ---- insert new data and back up ----
87960. check backup 3
87961. BackupableDBTest
87962. this seqnum guarantees the dummy file will be included in the backup as long as it is alive.
87963. the new backup fails because new table files clash with old table files from backups 4 and 5 (since write_buffer_size is huge, we can be sure that each backup will generate only one sst file and that a file generated by a new backup is the same as sst file generated by backup 4)
87964. see <https://github.com/facebook/rocksdb/issues/921>
87965. envs
87966. open DB, write, close DB, backup, restore, repeat
87967. all data should be there if we call with keep_log_files = true
87968. assert that data from backup 5 is still here (even though LATEST_BACKUP says 4 is latest)
87969. . and ..
87970. ---- restore every backup and verify all the data is there ----
87971. in last iteration, put smaller amount of data, so that backups can share sst files
87972. share_with_checksums
87973. FileManager
87974. new directory failure
87975. dummy
87976. **comment:** should also fail cleanup so the tmp directory stays behind
 label: code-design
87977. Behavior change: We now ignore LATEST_BACKUP contents. This means that we should have 5 backups, even if LATEST_BACKUP says 4.
87978. basically infinite
87979. since 5 meta is now corrupted, latest backup should be 4
87980. file 000007.sst was overwritten
87981. always rollover manifest for file add
87982. set up files
87983. write some data, backup, repeat
87984. get children failure
87985. ---- make sure it's empty ----
87986. set up envs
87987. iter 0 -- single threaded iter 1 -- multi threaded
87988. Some test cases do not actually create the test files (e.g., see DummyDB::live_files_) - for those cases, we mock those files' attributes so CreateNewBackup() can get their attributes.
87989. This test verifies we don't delete the latest backup when read-only option is set
87990. ----- case 2. - delete a file -----
87991. ---- make sure the data is there ---
87992. destroy old data
87993. reset all the defaults
87994. options
87995. this depends on the fact that 00007.sst is the first file created by the DB
87996. set up db options
87997. most tests will use multi-threaded backups
87998. restore 3
87999. Need to call this explicitly to delete tmp files
88000. created dir failure
88001. delete some backups -- this should leave only backups 3 and 5 alive
88002. context
88003. Filter expired blob indexes regardless of snapshots.
88004. new_value
88005. skip_until
88006. level
88007. namespace blob_db namespace rocksdb ROCKSDB_LITE

88009. Expired
88010. Unable to decode blob index. Keeping the value.
88011. CompactionFilter to delete expired blob index from base DB.
88012. namespace blob_db namespace rocksdb !ROCKSDB_LITE
88013. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88014. Iterator::Refresh() not supported.
88015. Test for data in SST
88016. Take a snapshot before compaction. Make sure expired blob indexes is filtered regardless of snapshot.
88017. First file
88018. The file shouln't be deleted
88019. Test for data in memtable
88020. The call simply pass through to base db. It should succeed.
88021. value_changed
88022. The default ttl extractor return no ttl for every key.
88023. Write to plain rocksdb.
88024. Issue manual compaction to trigger compaction filter.
88025. Second file
88026. Putting another blob should fail as ading it would exceed the blob_dir_size limit.

88027. namespace blob_db namespace rocksdb
88028. i = when to take snapshot
88029. The oldest simple blob file (i.e. blob_files[1]) has been selected for GC.
88030. The snapshot shouldn't see data in bfile
88031. Third file
88032. wait
88033. Test to verify that a NoSpace IOError Status is returned on reaching blob_dir_size limit.
88034. now
88035. The snapshot will see data in bfile, so the file shouldn't be deleted
88036. Fake blob index with TTL. See what it will do.
88037. Open as blob db. Verify it can read existing data.
88038. !ROCKSDB_LITE
88039. new_value
88040. very far in the future..
88041. DB should be empty.
88042. class BlobDBTest
88043. Verify blob db contain expected data and nothing more.
88044. The file is deleted this time
88045. Adding another 100 byte blob would take the total size to 264 bytes (2*132), which is more than 90% of blob_dir_size. So, the oldest file should be evicted and put in obsolete files list.
88046. Verify iterators
88047. VerifyDB use iterator to scan the DB.
88048. This test is no longer valid since we now return an error when we go over the configured blob_dir_size. The test needs to be re-written later in such a way that writes continue after a GC happens.
88049. context
88050. override all the keys
88051. Use mock env to stop wall clock.
88052. **comment:** Each stored blob has an overhead of about 42 bytes currently. So a small key + a 100 byte blob should take up ~150 bytes in the db.
 label: code-design
88053. run the same test for Get(), MultiGet() and Iterator each.
88054. **comment:** Each stored blob has an overhead of 32 bytes currently. So a 100 byte blob should take up 132 bytes.
 label: code-design
88055. Verify expired blob index are filtered.
88056. Verify normal Get
88057. Verify plain db return error for keys written by blob db.
88058. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88059. A black-box test for the t1l wrapper around rocksdb
88060. If true, the keys in this file all has TTL. Otherwise all keys don't have TTL.
88061. Mark file as obsolete by garbage collection. The file is not visible to snapshots with sequence greater or equal to the given sequence.
88062. The last sequence number by the time the file marked as obsolete. Data in this file is visible to a snapshot taken before the sequence.
88063. namespace blob_db namespace rocksdb ROCKSDB_LITE
88064. Compression type of blobs in the file
88065. has a pass of garbage collection successfully finished on this file obsolete_ still needs to do iterator/snapshot checks
88066. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88067. BlobIndex is a pointer to the blob and metadata of the blob. The index is stored in base DB as ValueType::kTypeBlobIndex. There are three types of blob index:
 kInlinedTTL: +-----+-----+-----+ | type | expiration | value | +-----+-----+-----+ | char | varint64 | variable size | +-----+-----+-----+
 kBlob: +-----+-----+-----+-----+ | type | file number | offset | size | compression | +-----+-----+-----+-----+
 +-----+ | char | varint64 | varint64 | varint64 | char | +-----+-----+-----+-----+-----+ | kBlobTTL: +-----+-----+-----+-----+-----+-----+-----+-----+ | type | expiration | file number | offset | size | compression | +-----+-----+-----+-----+-----+-----+-----+ | char | varint64 | varint64 | varint64 | char | +-----+-----+-----+-----+-----+-----+-----+
 There isn't a kInlined (without TTL) type since we can store it as a plain value (i.e. ValueType::kTypeValue).

88318. Replace all values by their reversed key
88319. change the lua script to removes all the key value pairs
88320. Issue full compaction and expect all keys which initial is < 'r' will be deleted as we keep the key value when we hit an error.
88321. namespace rocksdb
88322. **comment:** Fill one memtable per Put to make memtable use more memory.
 label: code-design
88323. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88324. Cache from table factories
88325. Expect the usage history of the table readers increases as we flush tables.
88326. Create an iterator and flush all memtables for each db
88327. Expect the usage history from the "usage_decay_point" is monotonically decreasing.
88328. Cache from DBImpl
88329. Cache from DBOptions
88330. Expect EQ as we didn't flush more memtables.
88331. Expect the usage of all memtables decreasing as we delete iterators.
88332. Expect the usage history is monotonically increasing
88333. Since the memory usage of un-flushed memtables is only affected by Put and flush, we expect EQ here as we only delete iterators.
88334. Since memtables are pinned by iterators, we don't expect the memory usage of all the memtables decreases as they are pinned by iterators.
88335. !ROCKSDB_LITE
88336. Start each test with a fresh DB
88337. we should have a place to store the result
88338. implicit
88339. Perform the following operations in limited scope

88340. Get (Quick check for persistence of previous database)
88341. Apply the similar "Append" to the parallel copy
88342. start from k2 this time.
88343. Append, Flush, Append, Get
88344. !ROCKSDB_LITE namespace
88345. Allows user to open databases with different configurations. e.g.: Can open a DB or a TtlDB, etc.
88346. namespace rocksdb
88347. Path to the database on file system
88348. Should release the snapshot and be aware of the new stuff now
88349. deterministic seed
88350. THE TEST CASES BEGIN HERE
88351. Constructor: specifies the rocksdb db
88352. Generate a random query (Append or Get) and random parameters
88353. Apply the query and any checks.
88354. All changes should be on disk. This will test VersionSet Get()
88355. NotFound is okay; just return empty (similar to std::map) But network or db errors, etc, should fail the test (or at least yell)
88356. Assumes that a non-existent key just returns <empty>
88357. Append, Get
88358. OpenDb opens a (possibly new) rocksdb database with a StringAppendOperator
88359. /StringLists represents a set of string-lists, each with a key-index. / Supports Append(list, string) and Get(list)
88360. Construct the desired string. Default constructor doesn't like '\0' chars. Verify that the string is right size. Use null delimiter instead of comma.
88361. Will store a local copy of all data in order to verify correctness
88362. Either key does not exist, or there is some error. Always return empty string (just for convention)
88363. !ROCKSDB_LITE
88364. Append string val onto the list defined by key; return true on success
88365. Snapshot should still be the same. Should ignore a4 and v4.
88366. The class for unit-testing
88367. Generate semi random keys/words from a small distribution.
88368. TtlDb is not supported in Lite Open a TtlDB with a non-associative StringAppendTESTOperator
88369. I omit the "assert(success)" checks here.
88370. should not be hit
88371. Append, Compact, Get
88372. TtlDb is not supported in Lite Run with TTL
88373. Append, Flush, Get
88374. deterministic seed; always get same results!
88375. Append, Flush, Compact, Get
88376. Always return false if s.ok() was not true
88377. Apply the rocksdb test-harness Append defined above apply the rocksdb append
88378. Returns the list of strings associated with key (or "" if does not exist)
88379. * * An persistent map : key -> (list of strings), using rocksdb merge. * This file is a test-harness / use-case for the StringAppendOperator. * * @author Deon Nicholas (dnicholas@fb.com) * Copyright 2013 Facebook, Inc.
88380. Verify it is still the correct size
88381. Generate a bunch of random queries (Append and Get)!
88382. The previous changes should be on disk (L0) The most recent changes should be in memory (MemTable) Hence, this will test both Get() paths.
88383. Check that the rocksdb result string matches the desired string
88384. Run with regular database
88385. Reopen the database (the previous changes should persist / be remembered)
88386. Apply the query and any checks.
88387. All three keys should have been found
88388. Generate a list of random keys and values
88389. Compact, Get
88390. namespace rocksdb
88391. ROCKSDB_LITE
88392. Env::Default() is a singleton so we can't grant ownership directly to the caller - we must wrap it first.

88504. RocksDB tests
88505. verify data
88506. Size should not change
88507. Check Get the list
88508. Repopulate some stuff Results in: [x, x, x, x, newbegin, z, x, aftera, x, newend, a, x]
88509. Added by Deon
88510. Exhaustive test of the Range() function
88511. Partial / Broken indices
88512. Block one: populate a single key in the database
88513. Test Trim [z, a, aftera, x] (do nothing)
88514. PushRight, Length, Index, Range
88515. Persistent, non-destructive
88516. We have: [sad, nota, zz, happy, z, beforeba2, ba2, a, aftera, x, newend]
88517. Simple Pushes (will yield: [v6, v4, v4, v1, v2, v3])
88518. Test InsertAfter end
88519. Testing Remove, RemoveFirst, RemoveLast
88520. Empty The length should not change
88521. Test out of bounds (empty) trim
88522. Check valid indices
88523. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88524. Set() with negative indices
88525. Exhaustive test for InsertBefore(), and InsertAfter()
88526. Block two: make sure changes were saved and add some other key
88527. Test InsertAfter
88528. [sad, a, happy, z, a, aftera, ...]
88529. Test bad value on InsertAfter
88530. Test removal from end
88531. Check
88532. operator== and operator<< are defined below for vectors (lists) Needed for ASSERT_EQ
88533. Bad indices (just out-of-bounds / off-by-one check)
88534. InsertBefore start of list InsertAfter end of list
88535. Used below for all Index(), PopRight(), PopLeft()
88536. Test Inserting before/after non-existent values Ensure that the length doesn't change
88537. namespace
88538. Test Regular Set
88539. [z, a, aftera]
88540. A series of pushes and insertions Will result in [newbegin, z, a, aftera, x, newend, a, a]
88541. Testing Insert, Push, and Set, in a mixed environment
88542. **comment:** / THE manual REDIS TEST begins here / THIS WILL ONLY OCCUR IF YOU RUN: ./redis_test -m
 label: test
88543. Make sure nothing weird happened.
88544. Testing duplicate values/pivots (multiple occurrences of 'a') [a, z, a, aftera, x, newend] [a, happy, z, a, aftera, ...]
88545. Check Length and Index() functions Check length
88546. Set on empty list (return false, and do not crash)
88547. Check range function and vectors Get the list
88548. **comment:** Test over-shooting (removing more than there exists)
 label: code-design
88549. **comment:** USAGE: "./redis_test" for default (unit tests) "./redis_test -m" for manual testing (redis command api) "./redis_test -m -d" for destructive manual test (erase db before use)
 label: test
88550. Simple PushRight
88551. Testing Trim, Pop
88552. Simple Pushes (will yield: [v6, v4, v4, v1, v2, v3])
88553. Removal from an empty-list
88554. namespace rocksdb
88555. Simple, non-negative indices
88556. Try removing ALL! REMOVE 0 will remove all!
88557. Check RemoveFirst (Remove the first two 'a') Results in [newbegin, z, aftera, x, newend, a]
88558. Test InsertBefore
88559. Exhaustive test of Set function
88560. Test out of bounds Set
88561. One last check (to make sure nothing weird happened) Size should not change
88562. Check for "want" argument in the argument list
88563. Invalid indices
88564. Empty Index check (return empty and should not crash or edit tempv)
88565. Exhaustive Trim test (negative and invalid indices) Will start in [newbegin, z, a, aftera, x, newend]
88566. !ROCKSDB_LITE
88567. We now have: [x, x, x, x, newbegin, z, aftera, newend, a]
88568. Should do nothing
88569. Destructive
88570. Only really removed 4
88571. Popping with empty list (return empty without error)
88572. Negative indices (i.e.: measured from the end)
88573. **comment:** Will run unit tests. However, if -m is specified, it will do user manual/interactive testing -m -d is manual and destructive (will clear the database before use)
 label: test
88574. Push some preliminary stuff [g, f, e, d, c, b, a]
88575. Range matches Index
88576. Simple PopLeft/Right test
88577. Insert on empty list (return 0, and do not crash)
88578. A series of pushes and insertions Will result in [newbegin, z, a, aftera, x, newend] Also, check the return value sometimes (should return length)
88579. / Allows the user to enter in REDIS commands into the command-line. / This is useful for manual / interactive testing / debugging. / Use destructive=true to clean the database before use. / Use destructive=false to remember the previous state (i.e.: persistent) / Should be called from main function.
88580. InsertBefore beginning of list InsertAfter end of list
88581. [sad, nota, zz, happy, z, a, ...] [sad, nota, zz, happy, z, ba, a, ...]
88582. Exhaustive test of the Index() function
88583. Sanity check (check the length; make sure it's 6)

88584. Last check
88585. [sad, a, zz, happy, z, a, aftera, ...]
88586. Set with negative indices
88587. Block three: Verify the changes from block 2
88588. Ensure Set worked correctly
88589. Test Multiple keys and Persistence
88590. A series of pushes and insertions Will result in [newbegin, z, a, aftera, x, newend]
88591. Out of bounds (return empty, no crash)
88592. Simply Test the Set() function
88593. PushLeft, Length, Index, Range
88594. Simple PushRight (should return the new length each time)
88595. Test bad value on InsertBefore
88596. Negative indices
88597. Now have: [z, a, aftera, x]
88598. ** A test harness for the Redis API built on rocksdb. ** USAGE: Build with: "make redis_test" (in rocksdb directory). * Run unit tests with: "./redis_test" * Manual/Interactive user testing: "./redis_test -m" * Manual user testing + restart database: "./redis_test -m -d" ** TODO: Add LARGE random test cases to verify efficiency and scalability ** @author Deon Nicholas (dnicholas@fb.com)
88599. [a]
88600. Test InsertBefore beginning
88601. C-version defined in <ctype.h>
88602. We currently have: [sad, nota, zz, happy, z, ba, a, aftera, x, newend] redis.Print("k1"); // manually check
88603. Verify
88604. Simple range
88605. **comment:** TODO: Right now, please use spaces to separate each word. In actual redis, you can use quotes to specify compound values Example: RPUSH mylist "this is a compound value"

88631. TEST 3: Issues a lots of deletes, but their density is not high enough to trigger compaction.
88632. Only one section of a file satisfies the compaction trigger
88633. randomize tests
88634. deterministic tests
88635. Simple test
88636. Insert "kNumDeletionTrigger * 0.95" deletions for every "kWindowSize" and verify compaction is not needed.
88637. !ROCKSDB_LITE
88638. Txn should commit
88639. Rollback to beginning of txn
88640. This Put outside of a transaction will conflict with the previous read
88641. txn1 can commit since txn2's delete hasn't happened yet (it's just batched)
88642. have to open default column family
88643. This Put outside of a transaction will conflict with the previous write
88644. Create N threads that use RandomTransactionInserter to write many transactions.
88645. This should not conflict in txn since the snapshot is later than the previous write (spoiler alert: it will later conflict with txn2).
88646. txn2 cannot commit since txn1 changed "4"
88647. txn should commit since the flushed table is still in MemtableList History
88648. Put a key which will conflict with the next txn using the previous snapshot
88649. Write some data to the db
88650. Put a random key so we have a MemTable to flush
88651. Set a new snapshot
88652. namespace rocksdb
88653. Put a random key so we have a memtable to flush
88654. Modify BBB before snapshot is taken
88655. 1
88656. Wait for all threads to run
88657. key "C" was modified in the db after txn's snapshot. txn will not commit.
88658. Verify transaction rollback works for untracked keys.
88659. Should commit since read/write was done after data changed
88660. force a memtable flush
88661. open the new column families
88662. Write to the untracked key outside of the transaction and verify it doesn't prevent the transaction from committing.
88663. Txn should not commit

88664. Conflicts with write done after snapshot taken
88665. verify that we track multiple writes to the same key at different snapshots
88666. Modify key after transaction start
88667. Verify txn did not commit
88668. Write some keys in a txn
88669. 2
88670. This will conflict since the snapshot is earlier than another write to ZZZ
88671. Rollback to 3
88672. Verify that txn1 cannot commit since A will still be conflict checked
88673. namespace
88674. Verify that data is consistent
88675. !ROCKSDB_LITE
88676. Write some keys to the db
88677. These keys do no conflict with existing writes since they're in different column families
88678. Write some keys to the db after the snapshot
88679. unexpected failure
88680. open DB with three column families
88681. Write to tracked key outside of the transaction and verify that the untracked keys are not written when the commit fails.
88682. Test 2 transactions writing to the same key in multiple orders and with/without snapshots
88683. Potentially conflicting writes
88684. Verify Txn Did not Commit
88685. Make sure at least some of the transactions succeeded. It's ok if some failed due to write-conflicts.
88686. Read and write with snapshot
88687. 3 4
88688. should not commit since txn2 wrote a key txn has read
88689. This Put outside of a transaction will conflict with a later write
88690. Create 2 new column families
88691. Read all keys via iter and lock them all
88692. Verify that transaction did not write anything
88693. txn should not commit since MemTableList History is not large enough
88694. This write will cause a conflict with the earlier batch write
88695. Test to make sure transactions work when there are no other writes in an empty db.
88696. force a memtable flush Since our test db has max_write_buffer_number=2, this flush will cause the first memtable to get purged from the MemtableList history.
88697. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88698. Setting the key-space to be 100 keys should cause enough write-conflicts to make this test interesting.
88699. Read and write without a snapshot
88700. Rollback to 2
88701. Verify that txn1 can commit since A isn't conflict checked
88702. try rollback again
88703. Txn should commit
88704. This Put outside of a transaction will conflict with the previous read
88705. should show the first txn log
88706. verify foo is locked by txn
88707. Verify that only "A" is locked
88708. Snapshot is now set
88709. This should not conflict in txn since the snapshot is later than the previous write (spoiler alert: it will later conflict with txn2).
88710. wait for friends
88711. txn2 has a smaller lock timeout than txn1's expiration, so it will time out
88712. should succeed since key was written before txn started
88713. assure that all thread are in the same write group
88714. Put a key which will conflict with the next txn using the previous snapshot
88715. Write some data to the db
88716. Put a random key so we have a MemTable to flush
88717. Set a new snapshot
88718. Verify A,B,D,E,F are still locked and C is not.
88719. verify that txn has "A" locked
88720. flush only cfb memtable
88721. Locked keys exist in both column family.
88722. Reinitialize txn1 and verify that Z gets unlocked
88723. **comment:** TODO this test needs to be updated with serial commits
 label: test
88724. Create a txn and verify we can only lock up to 3 keys
88725. Verify that "A" and "C" is still locked while "B" is not
88726. Upsize the buffer and verify the 3 latest dealocks are preserved.
88727. fails due to non-empty commit-time batch
88728. valid name set
88729. sleep override
88730. Should commit since read/write was done after data changed
88731. mix transaction writes and regular writes
88732. force a memtable flush
88733. Rollback the leaf transaction.
88734. Test txn1 and txn2 sharing a lock and txn2 trying to upgrade lock.
88735. Verify B is locked and A and C are not
88736. Snapshot was created before change to '2'
88737. heap should not show any logs
88738. Verify "A" "C" "B" are no longer locked
88739. Should fail since column family was dropped.
88740. Test txn1 trying to downgrade its lock.
88741. after memtable flush we can now release the log
88742. verify foo2 is locked by txn
88743. valid set name
88744. The iterator points to an unordered_multimap thus the test can not assume any particular order.
88745. commit time put
88746. Calculate next buffer len, plateau at 5 when 5 records are inserted.
88747. Write some keys to the db after the snapshot
88748. **comment:** TODO(myabandeh): Instantiate the tests with other write policies
 label: code-design

88749. In this test, txn1 should succeed committing, as the callback is called after txn1 starts committing.
88750. unexpected failure
88751. We want the last transaction in the chain to block and hold everyone back.
88752. Transaction should only write the keys that succeeded.
88753. txn2 should be expired out since txn1 waiting until its timeout expired.
88754. now we pause background work so that imm()s are not flushed before we can check their status
88755. ROCKSDB_LITE
88756. deleting transaction should unregister transaction
88757. Complete the cycle Tlen -> T1
88758. Header (12 bytes) + NOOP (1 byte) + 2 * 8 bytes for data.
88759. 10ms
88760. verify data txn data
88761. Should fail after encountering a write to Z in SST file
88762. This Put outside of a transaction will conflict with a later write
88763. Committing txn should release its locks and allow txn2 to proceed
88764. transaction writes have 10ms timeout, db writes have infinite timeout
88765. 100 minutes 1ms
88766. rollback to 1
88767. Txn should commit, but only write foo2 and foo3
88768. our log should be in the heap
88769. name too long
88770. The locked key is "foo" and is locked by txn1
88771. Downsize to 0 and verify the size is consistent.
88772. flush only cfa memtable
88773. commit in LOG B
88774. Verify A,B,D,E,F,H are still locked and C,G are not.
88775. According to db.h, doing a SingleDelete on a key that has been overwritten will have undefined behavior. So it is unclear what the result of fetching "A" should be. The current implementation will return NotFound in this case.
88776. log cannot be flushed because txn2 has not been committed
88777. force a memtable flush Since our test db has max_write_buffer_number=2, this flush will cause the first memtable to get purged from the MemtableList history.
88778. Copyright (c) 2011-present, Facebook, Inc. All rights reserved. This source code is licensed under both the GPLv2 (found in the COPYING file in the root directory) and Apache 2.0 License (found in the LICENSE.Apache file in the root directory).
88779. else commit it dummy put to inc db seq
88780. Rollback to 2
88781. but now our memtable should be referencing the prep section
88782. conflict
88783. commit old txn
88784. 100 minutes
88785. txn2 should be able to write to X since txn1 has expired
88786. We want the leaf transactions to block and hold everyone back.
88787. have to open default column family
88788. assert that cfa has a flush requested
88789. Conflict
88790. Create N threads that use RandomTransactionInserter to write many transactions.
88791. Verify A,B,F are still locked and C,D,E,G,H are not.
88792. Cannot lock B since it was written after the snapshot was set
88793. put txn2 prep section in this log
88794. make commit
88795. dummy put to inc db seq
88796. Should still fail after "downgrading".
88797. cfb should not be flushed becuze it has no data from LOG A
88798. make sure we are on a new log
88799. 1
88800. can't rename after prepare
88801. Set up a long wait for chain like this: T1 -> T2 -> T3 -> ... -> Tlen
88802. Now change "B".
88803. "C" was modified after txn's snapshot
88804. 1 ms
88805. shouldn't be able to prepare
88806. Test shared access between txns
88807. Force txn1 to expire
88808. We increase the db seq artificailly by a dummy Put. Check that this technique is effective and db seq is that same as ours.
88809. namespace
88810. verify that we track multiple writes to the same key at different snapshots
88811. Safety check to make sure the test actually ran
88812. Write some keys in a txn
88813. Use small commit cache to trigger lots of eviction and fast advance of max_evicted_seq_ will take effect after ReOpen
88814. This will conflict since the snapshot is earlier than another write to ZZZ
88815. find trans in list of prepared transactions
88816. value is readable from txn
88817. do prepare for a transaction dummy put to inc db seq
88818. All results should fail since there was a conflict
88819. Write some keys to the db
88820. Test txn1 holding an exclusive lock and txn2 trying to obtain shared access.
88821. nothing has been prepped yet
88822. Number of snapshots taken so far
88823. Conflict's with txn1's MultiGetForUpdate
88824. Upsize from 0 to verify the size is persistent.
88825. should show not dependency on logs
88826. Test 2 transactions writing to the same key in multiple orders and with/without snapshots
88827. Snapshot was set before D was written
88828. regular db read
88829. transaction should no longer be visible
88830. 3 4
88831. value is readable form txn
88832. 3 Rollback to 3
88833. Read all keys via iter and lock them all
88834. close

88835. Verify that "A", "B", "C" are still locked
88836. prepare
88837. We keep the list of txns committed before we take the last snapshot. These should be the only seq numbers that will be found in the snapshot
88838. Verify the size of the buffer and the single path.
88839. Set txn expiration timeout to 0 microseconds (expires instantly)
88840. Set up a wait for chain like this: Tn -> T(n*2) Tn -> T(n*2 + 1) So we have: T1 -> T2 -> T4 ... | > T5 ... | > T3 -> T6 ... | > T7 ... up to T31, then T[16 - 31] -> T1.
Note that Tn holds lock on floor(n / 2).
88841. Wait until all threads are waiting on each other.
88842. to restart the db
88843. Lock mostly for shared access, but exclusive 1/4 of the time.
88844. Rollback the last transaction.
88845. Column family is 1 or 0 (cfa).
88846. Verify A,B,C are locked
88847. Conflicts with previous GetForUpdate
88848. No snapshot created yet
88849. Should fail since column family was dropped
88850. roll to LOG B
88851. no longer is pprpared results
88852. txn1 has a lock timeout longer than txn2's expiration, so it will win
88853. Setting the key-space to be 100 keys should cause enough write-conflicts to make this test interesting.
88854. Take the final snapshot if it is not already taken
88855. Verify F is still locked and A,B,C,D,E,G,H are not.
88856. Complete the cycle T2 -> T1 with a shared lock.
88857. Take preliminary snapshots
88858. Rollback to beginning of txn
88859. kill and reopen
88860. To stress the data structure that maintain prepared txns, at each cycle we add a new prepare txn. These do not mean to be committed for snapshot inspection.
88861. Since we do not actually write to db, we mock the seq as it would be increased by the db. The only exception is that we need db seq to advance for our snapshots.
for which we apply a dummy put each time we increase our mock of seq.
88862. transaction put in two column families
88863. Create a cycle of size 2.
88864. regular put so that mem table can actually be flushed for log rolling
88865. Snapshot was set before C was written
88866. We compare whether the set of txns locking this key is the same. To do this, we need to sort both vectors so that the comparison is done correctly.
88867. In the above the latest change to AAAZZZ in handles[1] is delete.
88868. put new txn values
88869. The original value should still be read
88870. value is now available
88871. Should fail after encountering a write to S in SST file
88872. At each step we prepare a txn and then we commit it in the next txn. This emulates the consecutive transactions that write to the same key
88873. Drop first column family
88874. transaction expired!
88875. rollback to 2
88876. Test conflict checking against the very first write to a db. The transaction's snapshot is a seq 0 while the following write will have sequence 1.
88877. Conflicts with previous GetForUpdate. Since db writes do not have a timeout, this should eventually succeed when the transaction expires.
88878. Wait for some gap before taking the final snapshot
88879. According to db.h, doing a SingleDelete on a key that has been overwritten will have undefined behavior. So it is unclear what the result of fetching "F" should be.
The current implementation will return NotFound in this case.
88880. If the snapshot is taken, verify seq numbers visible to it. We redo it at each cycle to test that the system is still sound when max_evicted_seq_ advances.
88881. Verify that transaction wrote foo2 and foo3 but not foo
88882. namespace rocksdb
88883. re-locking same key shouldn't put us over the limit
88884. Verify transaction rollback works for untracked keys.
88885. cant prepare txn without name
88886. Reinitialize transaction to no long expire
88887. cant reset name
88888. Snapshot should not have changed yet.
88889. Conflicts with write done after snapshot taken
88890. Contrived case of shared lock of cycle size 2 to verify that a shared lock causing a deadlock is correctly reported as "shared" in the buffer.
88891. heap should still see first log
88892. new value is readable from txn
88893. * 1) use prepare to keep first log around to determine starting sequence * during recovery. * 2) insert many values, skipping wal, to increase seqid. * 3) insert final value into wal * 4) recover and see that final value was properly recovered - not * hidden behind improperly summed sequence ids
88894. Test WritePreparedTxnDB's IsInSnapshot against different ordering of snapshot, max_committed_seq_, prepared, and commit entries.
88895. Any other operation does
88896. Test conflict checking against the very first write to a db. The transaction's snapshot will have seq 1 and the following write will have sequence 1.
88897. Offset of the final entry in the dlock path from the root's txn id.
88898. open DB with three column families
88899. commit txn1
88900. **comment:** offset by 2 from the max depth to test edge case
label: test
88901. txn2 should not be able to write to X since txn1 has it locked
88902. **comment:** value is nolonger readable
label: code-design
88903. request a flush for all column families such that the earliest alive log file can be killed
88904. log has been marked
88905. Potentially conflicting writes
88906. transaction put
88907. Downsize the buffer and verify the 3 latest deadlocks are preserved.
88908. Make sure at least some of the transactions succeeded. It's ok if some failed due to write-conflicts.
88909. Same for snapshot cache size
88910. txn2 should now be able to write to X
88911. 3
88912. 4
88913. A Get does not generate the snapshot
88914. all data in LOG A resides in a memtable that has been requested for a flush
88915. Verify A,B,D,E,F are still locked and C,G,H are not.
88916. Complete the cycle T[16 - 31] -> T1

88917. create second cf
88918. crash
88919. we already committed
88920. This write will cause a conflict with the earlier batch write
88921. Special case for a deadlock path that exceeds the maximum depth.
88922. do all the writes
88923. write prep section to wal
88924. lock limit reached
88925. Should not conflict with txn2 since snapshot wasn't set until GetForUpdate was called.
88926. Verify that A and B are no longer locked
88927. If cur_txn is not started, do prepare for it.
88928. Lock keys in random order.
88929. issue rollback
88930. Rollback to 4
88931. heap should not care about prepared section anymore
88932. This Put outside of a transaction will conflict with the previous write
88933. Write a bunch of keys to db to force a compaction
88934. Verify snapshots get reinitialized correctly
88935. Open DB with a lock limit of 3
88936. Verify the exclusivity field of the transactions in the deadlock path.
88937. expired!
88938. txn should commit since the flushed table is still in MemtableList History
88939. Verify A,B,C,D,E,F are still locked
88940. Offset of each txn id from the root of the shared dlock tree's txn id.
88941. we should see txn1s log referenced by the memtables
88942. lock key in cfa
88943. verify non txn data
88944. Put a random key so we have a memtable to flush
88945. Modify BBB before snapshot is taken
88946. Untracked writes should succeed even though key was written after snapshot
88947. As an extra check, check if prepared set will be properly empty after they are committed.
88948. txn read
88949. Wait for all threads to run
88950. flush to next wal
88951. can't have duplicate name
88952. Column family is 0 (default) or 1.
88953. Test different table factories
88954. 500ms
88955. These keys do not conflict with existing writes since they're in different column families
88956. Snapshot has now been cleared
88957. open the new column families
88958. lock key in default cf
88959. Number of gaps applied so far
88960. 2
88961. heap should now show txn2s log
88962. Rollback to 3
88963. 100ms
88964. Modify key after transaction start
88965. We continue until max advances a bit beyond the snapshot.
88966. Verify that A is now unlocked
88967. exclusive
88968. Should succeed after verifying there is no write to X in SST file
88969. still not available to db
88970. transaction writes have an infinite timeout, but we will override this when we start a txn db writes have infinite timeout
88971. Verify that data is consistent
88972. Iterates backwards over path verifying decreasing txn_ids.
88973. cfb now has data from LOG A
88974. commit txn2
88975. Read and write without a snap
88976. flush default cf to create new log
88977. verify foo3 is locked by txn
88978. we should see that cfb now has a flush requested
88979. Leave some gap between the preliminary snapshots and the final snapshot that we check. This should test for also different overlapping scenarios between the last snapshot and the commits.
88980. The final snapshot that we will inspect
88981. Read and write with snapshot
88982. Test txn1 and txn2 sharing a lock and txn3 trying to obtain it.
88983. name too short
88984. issue rollback (marker written to WAL)
88985. Create 2 new column families
88986. Should commit since not expired
88987. 100ms txn timeout no longer infinite
88988. Verify A,B are locked and C is not
88989. Verify that A and B are still locked
88990. Test to make sure transactions work when there are no other writes in an empty db.
88991. txn1 should fail to commit since it is expired
88992. **comment:** Take some preliminary snapshots first. This is to stress the data structure that holds the old snapshots as it will be designed to be efficient when only a few snapshots are below the max_evicted_seq_.
label: code-design
88993. prepre transaction in LOG A
88994. "X" currently locked
88995. regular db put
88996. Rollback to 1
88997. Read and write without a snapshot
88998. data not in mem yet
88999. Verify that A is locked
89000. Should fail after encountering a write to S in memtable
89001. Verify A,B,E,F are still locked and C,D,G,H are not.

89002. T=0:Insert Set1.
89003. Puts num_entries starting from start_pos_map from kvmap_ into the database
89004. If TTL is non positive or not provided, the behaviour is TTL = infinity This test opens the db 3 times with such default behavior and inserts a bunch of kvs each time. All kvs should accumulate in the db till the end Partitions the sample-size provided into 3 sets over boundary1 and boundary2
89005. T=0:Open the db with ttl = 2 T=0:Insert Set1. Delete at t=2 T=1:Set1 should still be there
89006. Makes a write-batch with key-vals from kvmap_ and 'Write's it
89007. Choose carefully so that Put, Gets & Compaction complete in 1 second buffer
89008. T=0:Open the db with ttl = 2 T=0:Insert Set1. Delete at t=2 T=2:Set1 should not be there
89009. check all insertions done
89010. only column family 1 should be alive after 4 seconds
89011. T=2:Set1 should still be there
89012. Works on keys of the form "key<number>" Drops key if number at the end of key is in [0, kSampleSize_/3), Keeps key if it is in [kSampleSize_/3, 2*kSampleSize_/3), Change value if it is in [2*kSampleSize_/3, kSampleSize_) Eg. kSampleSize_=6. Drop:key0-1...Keep:key2-3...Change:key4-5...
89013. Resets the timestamp of a set of kvs by updating them and checks that they are not deleted according to the old timestamp
89014. dbiter should have found out kvmap_[st_pos]
89015. T=0>Delete at t=1 T=2: Set should not be there
89016. T=0:Open the db normally T=0:Insert Set1. Delete at t=1
89017. everything should be there after 1 second
89018. Sleeps for slp_tim then runs a manual compaction Checks span starting from st_pos from kvmap_ in the db and Gets should return true if check is true and false otherwise Also checks that value that we got is the same as inserted; and =knewValue if test_compaction_change is true
89019. Part dropped Part kept Part changed
89020. nothing should be there after 6 seconds
89021. Checks presence while opening the same db more than once with the same ttl Note: The second open will open the same db
89022. Similar to PresentDuringTTL but uses Iterator
89023. T=0: Insert. Delete at t=1 T=2: Should not be there
89024. Copyright (c) 2011 The LevelDB Authors. All rights reserved. Use of this source code is governed by a BSD-style license that can be found in the LICENSE file. See the AUTHORS file for names of contributors.
89025. Similar as SleepCompactCheck but uses TtlIterator to read from db
89026. db should be closed before opening again
89027. Open database with TTL support in read_only mode
89028. T=0: Insert. Delete at t=2
89029. Puts a set of values and checks its absence using Get after ttl
89030. class TtlTest
89031. T=0: Insert Set1. Delete at t=3 T=2 T=2: Insert Set1. Delete at t=5 T=4: Set1 should still be there
89032. Populates and returns a kv-map
89033. !ROCKSDB_LITE
89034. checks the whole kvmap_ to return correct values using KeyMayExist
89035. checks the whole kvmap_ to return correct values using MultiGet
89036. T=3: Set3 never deleted T=4: Sets 1,2,3 still there
89037. namespace rocksdb
89038. Keep keys not matching the format "key<NUMBER>"
89039. Open database with TTL support when TTL provided with db_ttl_ pointer
89040. Runs a manual compaction
89041. T=0. Delete at t=2 T=1: Set should be there
89042. T=0:Insert Set1. Delete at t=1 T=2: TTL logic takes precedence over TestFilter:-Set1 should not be there
89043. ensure that compaction is kicked in to always strip timestamp from kvs
89044. T=0: Insert. Delete at t=2 T=1: Set should be there
89045. T=0: Set1 never deleted T=1: Set1 still there
89046. T=0: Set deleted at t=3 T=2: Set should be there
89047. Insert some key-values which KeyMayExist should be able to get and check that values returned are fine
89048. Put a mock kv at the end because CompactionFilter doesn't delete last key
89049. A black-box test for the ttl wrapper around rocksdb
89050. Open with TestFilter compaction filter
89051. Similar to AbsentAfterTTL but uses Iterator
89052. Checks presence during ttl in read_only mode
89053. Checks user's compaction filter for correctness with TTL logic
89054. T=1: Set2 never deleted T=2: Sets1 & 2 still there
89055. compaction should take place always from level0 for determinism
89056. Checks whether WriteBatch works well with TTL Puts all kvs in kvmap_ in a batch and writes first, then deletes first half
89057. T=0: Insert. Delete at t=1
89058. Checks absence while opening the same db more than once with the same ttl Note: The second open will open the same db
89059. Puts a set of values and checks its presence using Get during ttl
89060. Checks presence while opening the same db more than once with bigger ttl
89061. Open database with TTL support when TTL not provided with db_ttl_ pointer
89062. namespace rocksdb

89210. error
89211. value_found
89212. Get a snapshot to avoid blob file get deleted between we fetch and index entry and reading from the file.
89213. Similar to OptimisticTransaction, we obtain latest_seq from base DB, which is guaranteed to be no smaller than the sequence of current key. We use a WriteCallback on write to check the key sequence on write. If the key sequence is larger than latest_seq, we know a new version is inserted and the old blob can be discarded. We cannot use OptimisticTransaction because we need to pass is_blob_index flag to GetImpl.
89214. allow_blob
89215. concrete at this time. also necessary to add to open_ttl_files_
89216. Key to check
89217. Hold a lock in the beginning to avoid updates to base DB during the call
89218. **comment:** TODO(yiwu): In case there are multiple writers the latest sequence would not be the actually sequence we are writing. Need to get the sequence from write batch after DB write instead.
label: code-design
89219. Inlined with TTL
89220. cache_only
89221. Double check the file is not obsolete by others
89222. Either the key is deleted or updated with a newer version which is inlined in LSM.
89223. **comment:** Get a snapshot to avoid blob file get deleted between we fetch and index entry and reading from the file. TODO(yiwu): For Get() retry if file not found would be a simpler strategy.
label: code-design
89224. reset oldest_file_evicted flag
89225. **comment:** TODO(yiwu): If index_entry is a PinnableSlice, we can also pin the same memory buffer to avoid extra copy.
label: code-design
89226. Release write_mutex_ before DB write to avoid race condition with flush begin listener, which also require write_mutex_ to sync blob files.
89227. Put as normal value

89228. **comment:** TODO(yiwu): correct the stats and expose it.
label: code-design
89229. **comment:** TODO(yiwu): Add an option to skip crc checking.
label: code-design
89230. Close a file if its size exceeds blob_file_size
89231. opened non-TTL blob file.
89232. Close a file by appending a footer, and removes file from open files list.
89233. when should oldest file be evicted: on reaching 90% of blob_dir_size
89234. Create a snapshot if there isn't one in read options. Return true if a snapshot is created.
89235. **comment:** TODO(yiwu): Should return column family id encoded in blob file after we add blob db column family support.
label: code-design
89236. Format of blob log file header (30 bytes): +-----+-----+-----+-----+-----+ | magic number | version | cf id | flags | compression | expiration range | +-----+-----+-----+-----+-----+ | Fixed32 | Fixed32 | Fixed32 | char | char | Fixed64 Fixed64 | +-----+-----+-----+-----+-----+ List of flags: has_ttl: Whether the file contain TTL data. Expiration range in the header is a rough range based on blob_db_options.ttl_range_secs.
89237. header include fields up to blob CRC
89238. Format of blob log file footer (48 bytes): +-----+-----+-----+-----+-----+ | magic number | blob count | expiration range | sequence range | footer CRC | +-----+-----+-----+-----+-----+ | Fixed32 | Fixed64 | Fixed64 + Fixed64 | Fixed64 + Fixed64 | Fixed32 | +-----+-----+-----+-----+-----+ The footer will be presented only when the blob file is properly closed. Unlike the same field in file header, expiration range in the footer is the range of smallest and largest expiration of the data in this file.
89239. Blob record format (32 bytes header + key + value): +-----+-----+-----+-----+-----+-----+ | key length | value length | expiration | header CRC | blob CRC | key | value | +-----+-----+-----+-----+-----+-----+ | Fixed64 | Fixed64 | Fixed64 | Fixed32 | Fixed32 | key len | value len | +-----+-----+-----+-----+-----+-----+ If file has has_ttl = false, expiration field is always 0, and the blob doesn't have expiration. Also note that if compression is used, value is compressed value and value length is compressed value length. Header CRC is the checksum of (key_len + val_len + expiration), while blob CRC is the checksum of (key + value). We could use variable length encoding (Varint64) to save more space, but it makes reader more complicated.
89240. 0x00248f37
89241. **comment:** A very rare event, in which the commit entry is updated before we do. Here we apply a very simple solution of retrying. TODO(myabandeh): do precautions to detect bugs that cause infinite loops
label: code-design
89242. We should not normally reach here
89243. It is committed and also not evicted from commit cache
89244. This is to avoid updating the snapshots_ if it already updated with a more recent version by a concurrent thread
89245. The list might get updated concurrently as we are reading from it. The reader should be able to read all the snapshots that are still valid after the update. Since the survived snapshots are written in a higher place before getting overwritten the reader that reads bottom-up will eventually see it.
89246. **comment:** TODO(myabandeh): implement lock-free commit_cache_
label: code-design
89247. then snapshot_seq < commit_seq overlapping range
89248. When advancing max_evicted_seq_, we move older entries from prepared to delayed_prepared_. Also we move evicted entries from commit cache to old_commit_map_ if it overlaps with any snapshot. Since prep_seq <= max_evicted_seq_, we have three cases: i) in delayed_prepared_, ii) in old_commit_map_, iii) committed with no conflict with any snapshot (i) delayed_prepared_ is checked above then (ii) cannot be the case only (iii) is the case: committed commit_seq <= max_evicted_seq_ < snapshot_seq => commit_seq < snapshot_seq
89249. initialized
89250. **comment:** Here we try to infer the return value without looking into prepare list. This would help avoiding synchronization over a shared map.
TODO(myabandeh): read your own writes TODO(myabandeh): optimize this. This sequence of checks must be correct but not necessarily efficient
label: code-design
89251. At this point we don't know if it was committed or it is still prepared
89252. else (ii) might be the case: check the commit data saved for this snapshot. If there was no overlapping commit entry, then it is committed with a commit_seq lower than any live snapshot, including snapshot_seq.
89253. When max_evicted_seq_ advances, move older entries from prepared_txns_ to delayed_prepared_. This guarantees that if a seq is lower than max, then it is not in prepared_txns_ and save an expensive, synchronized lookup from a shared set. delayed_prepared_ is expected to be empty in normal cases.
89254. Not evicted from cache and also not present, so must be still prepared
89255. continue the search if the next snapshot could be smaller than commit_seq
89256. We update the list concurrently with the readers. Both new and old lists are sorted and the new list is subset of the previous list plus some new items. Thus if a snapshot repeats in both new and old lists, it will appear upper in the new list. So if we simply insert the new snapshots in order, if an overwritten item is still valid in the new list is either written to the same place in the array or it is written in a higher place before it gets overwritten by another item. This guarantees a reader that reads the list bottom-up will eventually see a snapshot that repeats in the update, either before it gets overwritten by the writer or afterwards.
89257. We use this to identify how fresh are the snapshot list. Since this is done atomically with obtaining the snapshot list, the one with the larger seq is more fresh. If the seq is equal the full snapshot list could be different since taking snapshots does not increase the db seq. However since we only care about snapshots before the new max, such recent snapshots would not be included in the list anyway.
89258. snapshot_seq < prep_seq <= commit_seq => snapshot_seq < commit_seq
89259. If we do not store an entry in old_commit_map we assume it is committed in all snapshots. if commit_seq <= snapshot_seq, it is considered already in the snapshot so we need not to keep the entry around for this snapshot.
89260. **comment:** TODO(myabandeh) inc max in larger steps to avoid frequent updates
label: code-design
89261. Storing once is enough. No need to check it for other snapshots.
89262. continue the search if the next snapshot could be larger than prep_seq
89263. We only care about snapshots lower than max
89264. Returns true if commit_seq <= snapshot_seq
89265. After each eviction from commit cache, check if the commit entry should be kept around because it overlaps with a live snapshot. First check the snapshot cache that is efficient for concurrent access
89266. 10m entry, 80MB size
89267. Items could have moved from the snapshots_ to snapshot_cache_ before acquiring the lock. To make sure that we do not miss a valid snapshot, read snapshot_cache_ again while holding the lock.
89268. With each change to max_evicted_seq_ fetch the live snapshots behind it
89269. It is not committed, so it must be still prepared
89270. with any concurrent transactions. The easiest way to do this is to wrap all
89271. (ii) if it is the case: it is committed but after the snapshot_seq
89272. Update the size at the end. Otherwise a parallel reader might read items that are not set yet.
89273. **comment:** Then access the less efficient list of snapshots_
label: code-design
89274. **comment:** Insert them to a vector that is less efficient to access concurrently
label: code-design
89275. Then it is not committed yet
89276. Rewrite the entry with the index indexed_seq in the commit table with the commit entry <prep_seq, commit_seq>. If the rewrite results in eviction, sets the evicted_entry and returns true.
89277. Add the transaction with prepare sequence seq to the prepared list

89278. Add a new entry to `old_commit_map_` if `prep_seq <= snapshot_seq < commit_seq`. Return false if checking the next snapshot(s) is not needed. This is the case if the entry already added to `old_commit_map_` or none of the next snapshots could satisfy the condition. `next_is_larger`: the next snapshot will be a larger value
89279. **comment:** 2nd list for storing snapshots. The list sorted in ascending order. Thread-safety is provided with `snapshots_mutex_`.
label: requirement
89280. Rewrite the entry with the index `indexed_seq` in the commit table with the commit entry `new_entry` only if the existing entry matches the `expected_entry`. Returns false otherwise.
89281. Check whether the transaction that wrote the value with sequence number `seq` is visible to the snapshot with sequence number `snapshot_seq`
89282. A heap of prepared transactions. Thread-safety is provided with `prepared_mutex_`.
89283. **comment:** A set of long-running prepared transactions that are not finished by the time `max_evicted_seq` advances their sequence number. This is expected to be empty normally. Thread-safety is provided with `prepared_mutex_`.
label: requirement
89284. Already popped, ignore it.
89285. **comment:** The list sorted in ascending order. Thread-safety for writes is provided with `snapshots_mutex_` and concurrent reads are safe due to `std::atomic` for each entry. In x86_64 architecture such reads are compiled to simple read instructions. 128 entries TODO(myabandeh): avoid non-const static variables
label: requirement
89286. **comment:** unused
label: code-design
89287. Add the transaction with prepare sequence `prepare_seq` and commit sequence `commit_seq` to the commit map
89288. The largest evicted *commit* sequence number from the `commit_cache_`
89289. A map of the evicted entries from `commit_cache_` that has to be kept around to service the old snapshots. This is expected to be empty normally. Thread-safety is provided with `old_commit_map_mutex_`.
89290. Update when `delayed_prepared_.empty()` changes. Expected to be true normally.
89291. The version of the latest list of snapshots. This can be used to avoid rewriting a list that is concurrently updated with a more recent version.
89292. The list of live snapshots at the last time that `max_evicted_seq` advanced. The list stored into two data structures: in `snapshot_cache_` that is efficient for concurrent reads, and in `snapshots_` if the data does not fit into `snapshot_cache_`. The total number of snapshots in the two lists
89293. A heap with the amortized O(1) complexity for erase. It uses one extra heap to keep track of erased entries that are not yet on top of the main heap.
89294. `commit_cache_` must be initialized to zero to tell apart an empty index from a filled one. Thread-safety is provided with `commit_cache_mutex_`.
89295. Get the commit entry with index `indexed_seq` from the commit table. It returns true if such entry exists.
89296. (`heap_top() > seq`) Down the heap, remember to pop it later
89297. **comment:** TODO(myabandeh): avoid non-const static variables
label: code-design
89298. Update when `old_commit_map_.empty()` changes. Expected to be true normally.
89299. else value is already assigned
89300. `read_only`
89301. Resize the buffer to the target size and restore the buffer's idx
89302. Reversing the normalized vector returns the latest deadlocks first
89303. Next write occurs at a nonexistent path's slot
89304. Drop the deadlocks that will no longer be needed after the normalize
89305. callback
89306. **comment:** TODO(myabandeh): prevent the users from writing to txns after the prepare phase
label: code-design
89307. log ref
89308. any operations appended to this `working_batch` will be ignored from WAL
89309. We take the commit-time batch and append the Commit marker. The Memtable will ignore the Commit marker in non-recovery mode
89310. else value is already assigned
89311. Since the lifetime of the WriteBatch is the same as that of the transaction we cannot pin it as otherwise the returned value will not be available after the transaction finishes.

github_pulls_comments:

1. Looks good.
2. I can build & make test this on CentOS 7.4 with devtoolset-6 (GCC 6.3.1), but it fails when using devtoolset-7 (GCC 7.1.1). ``` In file included from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/write_batch_internal.h:12:0, from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/column_family.h:20, from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/version_set.h:31, from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/compaction.h:11, from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/compaction_iterator.h:12, from /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/builder.cc:16: /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/write_thread.h: In member function `std::mutex& rocksdb::WriteThread::Writer::StateMutex() const': /home/achristianson/workspace/nifi-minifi-cpp/thirdparty/rocksdb/db/write_thread.h:225:78: error: dereferencing type-punned pointer will break strict-aliasing rules [-Werror=strict-aliasing] return *static_cast<std::mutex*>(static_cast<void*>(&state_mutex_bytes)); ``` I would still merge this because I wasn't able to build with devtoolset-7 before this change, either. It's an improvement to have the newer versions, and I can't find any regressions.
3. **body:** @calebj can you define a top level variable for the path to civet and rocksdb and use that instead of the hardcoded path?
label: code-design
4. @calebj did anything in the process change? I can't build "No VERSION specified for WRITE_BASIC_CONFIG_VERSION_FILE()" Usually this indicates a version issue but I have version 3.10 on mac.
5. Weird. Nothing in the process should have changed. Where is that happening?

6. CMake Error at /usr/local/Cellar/cmake/3.10.0/share/cmake/Modules/WriteBasicConfigVersionFile.cmake:40 (message): No VERSION specified for WRITE_BASIC_CONFIG_VERSION_FILE() Call Stack (most recent call first):

```
/usr/local/Cellar/cmake/3.10.0/share/cmake/Modules/CMakePackageConfigHelpers.cmake:207 (write_basic_config_version_file) CMakeLists.txt:644
(write_basic_package_version_file) I don't see this in a rocksdb 5.8 clean checkout. I'm on OSX.
```
7. See if it works after the next push. I'm putting 5.8.6 in afresh and disabling the tests in a cleaner fashion.
8. @calebj Re the next push, did you force push into that last commit?
9. I did. The new commit messages reflect the new version, too.
10. @calebj the travis failure shows you what we've been seeing on clang 9 <https://travis-ci.org/apache/nifi-minifi-cpp/jobs/309102064> It might be better to separate the upgrade of civet and rocksdb?
11. @calebj I see the change. I'll attempt to merge this into master and run the build before pushing. thanks!
12. @calebj I merged this already, but the sync hasn't occurred. Sometimes we need to perform another merge to break it free <https://git-wip-us.apache.org/repos/asf?p=nifi-minifi-cpp.git> for reference.
13. I see it in df353561c8a8a0a0d1178a76f03b966b44542834. Hopefully that commit hash will resolve once the sync is complete. Thanks!

github_pulls_reviews:

jira_issues:

1. **summary:** Upgrade civetweb and rocksdb

description: These upgrades to the latest stable releases of civetweb ([v1.10|<https://github.com/civetweb/civetweb/releases/tag/v1.10>]) and RocksDB ([v5.8|<https://github.com/facebook/rocksdb/releases/tag/v5.8>]) bring numerous improvements. They might solve any issues similar to those in MINIFICPP-262. For civet, the most notable is OpenSSL v1.1 support. It was partially backported to the version in the minifi tree (1.9.1), but still had issues matching some OpenSSL v1.1 interface changes. Civetweb release v1.10 has complete and official support. RocksDB v5.8 comes with the following bugfixes: * Fix wrong latencies in rocksdb.db.get.micros, rocksdb.db.write.micros, and rocksdb.sst.read.micros. * Fix incorrect dropping of deletions during intra-L0 compaction. * Fix transient reappearance of keys covered by range deletions when memtable prefix bloom filter is enabled. * Fix potentially wrong file smallest key when range deletions separated by snapshot are written together.

You can merge this pull request into a Git repository by running: \$ git pull <https://github.com/NiFiLocal/nifi-minifi-cpp> MINIFICPP-303 Alternatively you can review and apply these changes as the patch at: <https://github.com/apache/nifi-minifi-cpp/pull/185.patch> To close this pull request, make a commit to your master/trunk branch with (at least) the following in the commit message: This closes #185 -----
2. Caleb, did this solve your issues for MINIFICPP-262? I gathered that was no longer an issue and thus we are upgrading just to upgrade, correct?
3. Yes, it solved both of the problems I was having on Arch when I dropped the new versions in. I just didn't submit them as a patch until now.
4. [~calebj] Your comment in 262 was "I can't reproduce the issue either on a fresh Trusty VM," but yet you were having issues on Cloud9. Did this solve the Cloud9 issue for you ? I saw your comment, "It might solve." I don't want to close 262 until I can verify from [~christiansanson] that 262 was a problem he could/can replicate and is still a problem. Sorry I said, "before merging," but I don't plan to hold merging this to get an understanding. The plan is still to merge after some testing.
5. Github user achristianson commented on the issue: <https://github.com/apache/nifi-minifi-cpp/pull/185> Looks good.
